Nucleotides are released from cells in response to mechanical stimuli and signal in an autocrine/paracrine manner through cell surface P2 receptors. P2rx7−/− mice exhibit diminished appositional growth of long bones and impaired responses to mechanical loading. We find that calvarial sutures are wider in P2rx7−/− mice. Functional P2X7 receptors are expressed on osteoblasts in situ and in vitro. Activation of P2X7 receptors by exogenous nucleotides stimulates expression of osteoblast markers and enhances mineralization in cultures of rat calvarial cells. Moreover, osteogenesis is suppressed in calvarial cell cultures from P2rx7−/− mice compared with the wild type. P2X7 receptors couple to production of the potent lipid mediators lysophosphatidic acid (LPA) and prostaglandin E2. Either an LPA receptor antagonist or cyclooxygenase (COX) inhibitors abolish the stimulatory effects of P2X7 receptor activation on osteogenesis. We conclude that P2X7 receptors enhance osteoblast function through a cell-autonomous mechanism. Furthermore, a novel signaling axis links P2X7 receptors to production of LPA and COX metabolites, which in turn stimulate osteogenesis.

Introduction

The skeletal system develops and adapts throughout life in response to hormones, cytokines, and external factors such as mechanical loading. Maintenance of bone mass in adults is a dynamic process that involves a balance of resorption by osteoclasts and formation by osteoblasts. For >100 yr, it has been known that bone is remodeled in accordance with the stresses placed upon it (Frost, 2001). Unloading of the skeleton decreases osteogenesis, and mechanotransduction is now recognized as one of the major factors regulating skeletal mass (Robling et al., 2006).

Nucleotides, such as ATP, are thought to be key mediators in the response of bone cells to mechanical stimuli (Dixon and Sims, 2000; Robling et al., 2006). Many cells release ATP when subjected to stretch or fluid shear (Romanello et al., 2001; Genetos et al., 2005; Riddle et al., 2007). Extracellular ATP can then signal through P2 nucleotide receptors present on various cell types including osteoblasts. There are two subtypes of P2 receptors, P2X (ligand-gated cation channels) and P2Y (G protein–coupled receptors; Burnstock, 2007). Osteoblasts express multiple subtypes of P2X and P2Y receptors (Dixon and Sims, 2000; Hoebertz et al., 2000), but the mechanistic basis of nucleotide effects on bone is not clear.

P2X7 receptors function not only as nonselective cation channels but can also induce the formation of large membrane pores, which allow passage of molecules with size up to 900 kD (North, 2002; Khakh and North, 2006). Pore formation may arise from dilation of the channel caused by recruitment of additional subunits. However, recent evidence supports the possibility that P2X7 receptor activation leads to opening of a distinct pore protein in the plasma membrane (Pelegrin and Surprenant, 2006).

P2X7 receptors have been implicated in skeletal remodeling and mechanotransduction. P2rx7−/− mice exhibit decreased periosteal bone formation in long bones without a difference in length (Ke et al., 2003). Moreover, P2rx7−/− mice show reduced osteogenesis in response to mechanical loading (Li et al., 2005). We have recently shown that activation of P2X7 receptors induces dynamic membrane blebbing in a subpopulation of calvarial cells (Panupinthu et al., 2007). Despite these findings that link P2X7 receptors to anabolic effects on...
the skeleton, it is not known how these receptors influence osteogenesis. Moreover, it is not known whether the phenotype of the P2rx7−/− mouse is caused by an intrinsic defect in osteoblasts or by an indirect effect mediated by other cell types. In this regard, the P2X7 receptor is expressed in cells of the monocyte/macrophage lineage, including osteoclasts (Naemsch et al., 2001), as well as some endocrine cell types.

In the present study, we discovered a cell-autonomous role for P2X7 receptors in bone formation. We show that activation of P2X7 receptors leads to production of lysophosphatidic acid (LPA) as well as cyclooxygenase (COX) metabolites. These lipid mediators then up-regulate expression of osteoblast marker genes and stimulate mineralization. Thus, we establish the existence of a P2X7-LPA signaling axis that regulates osteoblast differentiation and osteogenesis during skeletal remodeling and mechanotransduction.

Results

Characteristics of calvariae from P2rx7−/− mice

Mice lacking P2rx7 exhibit decreased periosteal bone formation in the tibia and insensitivity of the ulna to mechanical loading (Ke et al., 2003; Li et al., 2005). To further explore the role of this receptor in osteogenesis, we examined the calvariae of wild-type and P2rx7−/− mice using microcomputed tomography. Unlike long bones, which form primarily through endochondral ossification, calvariae form through intramembranous ossification and are not subject to weight bearing. Surprisingly, we found that calvarial sutures were wider in P2rx7−/− mice compared with age- and sex-matched wild-type controls (Fig. 1 A). There was no significant difference in calvarial thickness in the region of the suture. Quantitative analysis revealed that the cross sectional suture area between parietal bones was ~40% greater in P2rx7−/− mice compared with the wild type (Fig. 1 B). Thus, P2rx7−/− mice exhibit calvarial defects, which are evident at sutures which experience tensile strain caused by intracranial pressure (Henderson et al., 2005).

To investigate whether calvarial cells in situ express functional P2X7 receptors, we assessed P2X7-induced pore formation (Fig. 1 C). Calvariae were removed from newborn wild-type and P2rx7−/− mice. Parietal bones were incubated in 300 μM 2′,3′-O-(4-benzoylbenzoyl)-ATP (BzATP; a relatively potent P2X7 agonist) or vehicle. P2X7 agonist caused uptake of ethidium bromide (indicating pore formation) by cells on the surface of calvariae from wild-type but not P2rx7−/− mice (right, red). Ethidium bromide uptake in vehicle-treated calvariae from wild-type and P2rx7−/− mice was virtually undetectable (not depicted). Data are representative of four fields each from six to eight mice from three different litters. Bar, 100 μm.

Functional P2X7 receptors are expressed in osteoblasts in vitro

Previous in vitro studies have revealed that a subpopulation of rodent calvarial cells expresses P2X7 receptors (Ke et al., 2003; Panupinthu et al., 2007). In this paper, we found that a subpopulation of marrow stromal cells isolated from rat long bones also expresses functional P2X7 receptors (Fig. S1, available at http://www.jcb.org/cgi/content/full/jcb.200708037/DC1). However, the identity of these subpopulations is not known. Moreover, it has not been established whether the effects of P2X7 receptors...
on bone formation in vivo are osteoblast autonomous. To investigate these questions, we used a well-characterized bone formation assay using calvarial cells isolated from newborn rodents. In rat calvarial cell cultures, supplementation of the medium with 50 μg/ml ascorbic acid and 2 mM β-glycerophosphate induced osteoblast differentiation and bone nodule formation (Fig. 2A). Alkaline phosphatase (ALP) activity was detected using cytochemical staining (red). Mineral deposition was revealed by staining with silver nitrate solution (von Kossa; black). After 14 d of supplementation, mineralized areas were centrally located within regions displaying ALP activity, indicating the presence of active osteoblasts.

We first determined expression of functional P2X7 receptors in differentiated rat calvarial cell cultures using the pore formation assay. Uptake of propidium iodide was monitored after treatment with 300 μM BzATP or vehicle (control). We examined confocal images in an xy plane near the midregion of nodules (25 μm above the substrate). Nuclei were visualized with SYTO-13 (Fig. 2B, left). BzATP induced uptake of propidium iodide (Fig. 2B, middle), and colocalization of SYTO-13 and propidium iodide was observed (Fig. 2B, right). Intensity profiles along the dotted lines revealed colocalization of SYTO-13 and propidium iodide in cultures treated with BzATP but not in control. These data establish the presence of functional P2X7 receptors in bone nodule cells. When images were examined in an xy plane at the top of the nodule (in this case, 30 μm above the substrate), robust pore formation was observed in response to BzATP (Fig. 2C, top). In contrast, cells located in the monolayer between nodules (6 μm above the substrate) did not exhibit pore formation, indicating that these less differentiated cells do not express functional P2X7 receptors (Fig. 2C, bottom).

We next evaluated P2X7 receptor expression during the differentiation of rat and murine calvarial cells. When medium was supplemented with ascorbic acid and β-glycerophosphate, expression of P2rx7 in cultures from wild-type mice was found to increase 2.9 ± 0.3-fold over 14 d (assessed using quantitative real-time RT-PCR; n = 3 independent experiments analyzed by paired t test; P < 0.05). Expression of P2rx7 also increased during the differentiation of rat calvarial cells (levels assessed at days 0 and 7; n = 3 independent experiments; P < 0.05). Collectively, these data demonstrate that the calvarial cells responsible for osteogenesis in vivo and in vitro express functional P2X7 receptors.
formation of bone nodules, mineralized and ALP-positive areas were assessed at 7-d intervals. As expected, both parameters increased in the presence of ascorbic acid and β-glycerophosphate over 28 d in control cultures. 100 μM BzATP stimulated mineralization and ALP activity (Fig. 3 A). Analysis of mineralized area indicated that BzATP significantly enhanced the extent of mineralization compared with the control from 14–28 d, with a 40% increase at day 28 (Fig. 3 B). In addition, BzATP accelerated the development of ALP activity, with significant increases at 14 and 21 d but reaching the same level by 28 d (Fig. 3 C). Data from all bone formation assays were pooled from at least three independent experiments.

We next assessed expression of osteoblast marker genes in rat calvarial cell cultures using real-time RT-PCR. Consistent with its effects on nodule formation, 100 μM BzATP significantly up-regulated levels of transcripts encoding osterix and osteocalcin at 14 and 28 d (Fig. 3, D and E). Expression of the gene encoding osteocalcin (marker of late-stage osteoblast differentiation) was dramatically enhanced by BzATP at 28 d. Thus, BzATP acts on cells of the osteoblast lineage to up-regulate the genes encoding osterix and osteocalcin and to promote osteogenesis.

It is known that BzATP activates several P2 nucleotide receptors in addition to P2X7 (North, 2002). Thus, we investigated which P2 receptor subtypes mediate the stimulatory effects of BzATP on bone formation using UTP, an agonist for several P2Y receptors but ineffective at all P2X receptors (Burnstock, 2007). Moreover, ALP present on the surface of osteoblasts can hydrolyze nucleotides, causing release of Pi that promotes mineralization at sufficiently high concentrations. Although 100 μM BzATP increased mineral deposition and ALP activity, 100 μM UTP did not (Fig. 3, F–H). Similarly, an equivalent concentration of Pi...
(300 μM) had no effect. Thus, activation of P2Y receptors is not sufficient to stimulate osteogenesis, and the modest increase in Pi levels from nucleotide hydrolysis cannot account for the enhancement of mineralization observed.

To evaluate the role of endogenous nucleotides, rat calvarial cell cultures were differentiated in the absence of exogenous nucleotides with and without apyrase, a diphosphohydrolase that breaks down extracellular nucleotides. 10 units/ml apyrase decreased ALP activity (at 14 d, ALP-positive area was 50 ± 3% in control cultures vs. 39 ± 2% in cultures treated with apyrase; n = 3 independent experiments; P < 0.05). This finding is consistent with constitutive release of endogenous nucleotides from calvarial cells, which has been reported previously in an osteoblast-like cell line (Buckley et al., 2003).

**Figure 4. Reduced osteogenesis in cultures of calvarial cells from P2rx7−/− mice.** (A) Calvarial cells from wild-type and P2rx7−/− mice were cultured in medium containing physiological concentrations of Ca²⁺ and Mg²⁺. At day 0, culture medium was supplemented with ascorbic acid and β-glycerophosphate without exogenous nucleotides. Images show representative micromass cultures (equivalent fields). Bar: 0.5 cm. (B and C) Calvarial cell cultures from P2rx7−/− mice showed decreased mineral deposition (B) and delayed development of ALP activity (C) compared with wild-type cultures. Data are means ± SEM (n = 3 independent preparations). *P < 0.05. (D) DNA content of selected cultures was assessed using HOECHST 33342. Data are expressed relative to DNA content in wild-type cultures at day 0. As expected, DNA content increased from day 0 to 28, however there was no significant difference between cultures from wild-type and P2rx7−/− mice. Data are means ± SEM (n = 3–4 independent preparations). *, significant difference compared with day 0 (P < 0.05).

**Gene expression in cultures of calvarial cells from wild-type and P2rx7−/− mice**
To further investigate the role of P2X7 receptors in osteogenesis, we assessed expression levels of marker genes in cultures from wild-type and P2rx7−/− mice at 7-d intervals up to 28 d (Fig. 4 D). These data and those presented in Fig. 3 indicate that P2X7 receptors stimulate bone formation, possibly by enhancing osteoblast differentiation.

**Diminished mineralization and ALP activity in cultures from P2rx7−/− mice**
To compare nodule formation in cultures of calvarial cells from wild-type and P2rx7−/− mice. Medium was supplemented with ascorbic acid and β-glycerophosphate without exogenous nucleotides (in contrast to the experiments shown in Fig. 3, where BzATP was added). Cultures from P2rx7−/− mice showed a marked decrease in mineralization compared with wild-type murine cultures, with a 33% reduction at day 28 (Fig. 4, A and B). Moreover, the development of ALP activity was delayed in cultures from P2rx7−/− mice, with significantly less activity at 14 and 21 d (Fig. 4, A and C). Thus, osteogenesis is diminished in cultures from P2rx7−/− mice, supporting a role for P2X7 receptors in stimulating bone formation. Moreover, the fact that this difference was observed in the absence of exogenous nucleotides provides further evidence for constitutive nucleotide release.

We next investigated whether the difference in osteogenesis in cultures from wild-type and P2rx7−/− mice could arise from changes in the proliferation or survival of calvarial cells. However, DNA analysis revealed no significant difference in cell numbers between P2rx7−/− and wild-type cultures at 0 and 28 d (Fig. 4 D). These data and those presented in Fig. 3 indicate that P2X7 receptors stimulate bone formation, possibly by enhancing osteoblast differentiation.

**Gene expression in cultures of calvarial cells from wild-type and P2rx7−/− mice**
To explore the role of P2rx7 in osteoblast differentiation, we assessed expression levels of marker genes in cultures from wild-type and P2rx7−/− mice at 7-d intervals up to 28 d, without exogenous nucleotides. There was no significant difference in levels of Runx2 transcripts in wild-type and P2rx7−/− cultures (Fig. 5). Osterix transcript levels were dramatically suppressed from 7–21 d in P2rx7−/− cultures (Fig. 5). Expression of the gene encoding bone sialoprotein was diminished fivefold in P2rx7−/− cultures at 7 d, closely reflecting the changes in osterix expression. Furthermore, transcript levels of osteocalcin were markedly suppressed from 7–21 d in P2rx7−/− cultures (2–13-fold).

Because there is lineage allocation during differentiation of mesenchymal cells, we next investigated the expression of adipocyte and chondrocyte markers. At day 7, transcript levels of the adipocyte marker peroxisome proliferator-activated

receptor γ (PPARγ) were significantly increased (approximately threefold) in cultures from P2rx7−/− compared with wild-type mice (Fig. 5). Similarly, expression of the gene encoding lipoprotein lipase, which is regulated by PPARγ, was increased in P2rx7−/− cultures at day 7. However, there were no differences in levels of chondrocyte markers. Data are means ± SEM (n = 3 independent preparations). * Significant difference compared with wild type at the corresponding time (P < 0.05).

differentiation in P2rx7−/− cell cultures. Collectively, our findings from the rat and murine systems (Figs. 2–5) establish that P2X7 receptors promote osteogenesis through a cell-autonomous mechanism by directing cells toward the osteoblast lineage.

**P2X7 receptors couple to production of LPA through activation of phospholipases**

In our previous study, lipid signaling was implicated in the pathway underlying P2X7-induced membrane blebbing of calvarial cells (Panupintu et al., 2007). Therefore, we used a biochemical
approach to directly investigate whether P2X7 receptor activation leads to the production of LPA. Rat calvarial cells were labeled with [14C]glycerol overnight and then incubated with 300 μM BzATP or vehicle (control) for 20 min. Cells were collected and total lipids were separated using thin layer chromatography (Fig. 6 A). BzATP induced a significant increase in levels of phosphatidic acid (PA; Fig. 6 B, top). The phospholipase D (PLD) inhibitor 1-butanol (1% vol/vol) completely inhibited the production of phosphatidic acid induced by BzATP. In contrast, its inactive analogue tert-butanol had little effect. Moreover, 10 μM of the PLA2 inhibitor bromoeno lactone (BEL) had no significant effect on phosphatidic acid synthesis. Importantly, BzATP stimulated production of LPA (Fig. 6 B, middle). This effect was abolished by 1-butanol as well as by BEL, whereas tert-butanol had no significant effect. In the absence of phospholipase inhibitors, BzATP caused a significant decrease in levels of phosphatidylcholine (PC; Fig. 6 B, bottom), which is consistent with phosphatidylcholine being a preferred substrate of PLD (Frohman et al., 1999). In accord, there were no significant changes in phosphatidylethanolamine levels (Fig. S2, available at http://www.jcb.org/cgi/content/full/jcb.200708037/DC1).

As in rat calvarial cells, BzATP stimulated production of LPA in wild-type murine cells (Fig. 6 C, left), together with a corresponding decrease in phosphatidylcholine levels (Fig. 6 C, right). In contrast, BzATP failed to induce LPA production in cells from P2xr7−/− mice. These data establish directly that activation of P2X7 receptors leads to production of the potent lipid mediator LPA through stimulation of PLD and PLA2 activity.

Role of lipid signaling pathways in mediating BzATP-induced osteogenesis

LPA acts through the specific G protein–coupled receptors LPA1–5. LPA1 is widely distributed and appears to be the predominant receptor subtype present in cells of the osteoblast lineage (Masiello et al., 2006). We tested directly whether LPA signaling is involved in P2X7-induced osteogenesis.

We began by assessing the effectiveness and specificity of the LPA1/3 receptor antagonist VPC-32183 (Heasley et al., 2004) in rat calvarial cell cultures. Because LPA receptors signal through PLC (Mills and Moolenaar, 2003), we monitored LPA-induced elevation of [Ca2+]i. Figure 7 shows time course of [Ca2+]i changes in the whole field. Data are expressed as percentages of the basal fluorescence intensity at time 0. Cells were challenged with 100 nM LPA and 100 μM UTP (which activates calcium mobilizing P2Y receptors on osteoblasts). [A] Micrographs of a representative field in a vehicle-treated culture show basal fluorescence (a), peak of the response to LPA (b), before adding UTP (c), and peak response to UTP (d). Both LPA and UTP caused transient increase in the fluorescence intensity of flou-4. Bar, 10 μm. [B] Graphs show time course of [Ca2+]i changes in the whole field. Data are expressed as percent-ages of the basal fluorescence intensity at time 0. Cells were challenged with 100 nM LPA and 100 μM UTP at the times indicated by the horizontal bars beneath the graphs. a–d indicate the times of capture of the images shown in A. (C) Peak amplitudes of Ca2+ responses to LPA and UTP were calculated. Data are the maximum elevation above basal expressed as a percentage of basal. VPC-32183 significantly suppressed the Ca2+ response induced by 100 nM LPA (left) but had no eff ect on the subsequent response to UTP (right). Data are means ± SEM (n = 3 independent preparations). *, significant effect of VPC-32183 compared with vehicle (P < 0.05).
BzATP on mineral deposition (Fig. 8, A and B). In contrast, the LPA receptor antagonist had only a modest effect on the BzATP-induced increase in ALP activity (Fig. 8, A and C). In addition, VPC-32183 itself had no effect on cell numbers (Fig. S3 A, available at http://www.jcb.org/cgi/content/full/jcb.200708037/DC1). In some experiments, total RNA was collected and real-time RT-PCR analysis was performed. VPC-32183 abolished the increase in expression of osterix and osteocalcin induced by BzATP (Fig. 8 D). These data indicate that BzATP-induced osteogenesis is dependent on pathways downstream of LPA receptors.

It is possible that BzATP-induced osteogenesis involves signaling pathways in addition to LPA. Activation of PLA2 leads to production of eicosanoids such as prostaglandin E2 (PGE2), which is known to stimulate bone formation in vitro and in vivo (Flanagan and Chambers, 1992; Yoshida et al., 2002). Therefore, we determined the effects of BzATP on synthesis of PGE2. After 5 min, 300 μM BzATP significantly increased PGE2 release from rat calvarial cell cultures (Fig. 9 A). 10 μM ibuprofen, which inhibits both COX-1 and -2, blocked the effects of BzATP on PGE2 synthesis. In contrast, VPC-32183 did not inhibit PGE2 production (n = 3 independent experiments; unpublished data), indicating that BzATP-induced prostaglandin synthesis does not depend on LPA receptor activation.

We next explored the role of COX in P2X7-induced osteogenesis. Rat calvarial cells were differentiated with or without 100 μM BzATP, and in the presence of 10 μM ibuprofen, 10 μM NS-398 (a selective COX-2 inhibitor), or vehicle for 14 d. Like VPC-32183, NS-398 itself had no effect on cell numbers (Fig. S3 B). Again, BzATP stimulated mineralization and ALP activity (Fig. 9 B). Similar to the actions of VPC-32183, COX inhibitors abolished the effects of BzATP on mineralization and osteocalcin expression while only slightly suppressing ALP activity (Fig. 9, C–E). Activation of P2X7 receptors did not significantly alter expression of COX-2 at 14 d (mRNA levels in BzATP-treated cells were 122 ± 5% of control; n = 3 independent experiments; P > 0.05). However, it is possible that BzATP transiently alters COX-2 expression at earlier times. Collectively, these data implicate eicosanoid signaling along with LPA in mediating P2X7-induced osteogenesis (Fig. 10).

**Discussion**

**P2X7 receptors promote osteogenesis in vivo and in vitro**

Mesenchymal cells within cranial sutures proliferate and differentiate to sustain the osteoblast population and form new bone (Morris-Kay and Wilkie, 2005), processes which are stimulated at least in part by mechanical tension (Hou et al., 2007). In the present study, microcomputed tomography revealed wider sutures in adult P2rx7−/− mice compared with the wild type, which is consistent with reduced osteogenesis at the suture. In contrast, there was no apparent difference in the size of fontanelles of wild-type and P2rx7−/− mice at birth (unpublished data), although P2X7 receptors are expressed in the cranial bones and vertebrae of embryonic day 19 rat embryos (Collo et al., 1997). This phenotype is in keeping with the characteristics of long bones in P2rx7−/− mice, which display reduced periosteal

---

**Figure 8.** VPC-32183 suppresses BzATP-enhanced mineralization. During differentiation, rat calvarial cells were treated with 1 μM VPC-32183 or its vehicle and 100 μM BzATP or its vehicle (control) for 14 d. (A) Cultures were fixed and stained for ALP activity and mineral deposition. Bar, 1 mm. (B) VPC-32183 suppressed BzATP-enhanced mineralization without significantly affecting control cultures. (C) ALP activity was not significantly affected by VPC-32183. (D) Expression levels of genes encoding osterix and osteocalcin were analyzed using real-time RT-PCR. Data are expressed relative to values in vehicle-treated control cultures. VPC-32183 abolished the effects of BzATP on osterix and osteocalcin expression. Data are means ± SEM (n = 3 independent preparations). *, significant effect of BzATP compared with control (P < 0.05).

Having demonstrated the effectiveness and specificity of VPC-32183 in osteoblasts, we next investigated the effects of this LPA receptor antagonist on BzATP-induced osteogenesis. Rat calvarial cells were differentiated with or without 100 μM BzATP, and cultures were also treated with 1 μM VPC-32183 or its vehicle for 14 d. As expected, BzATP enhanced mineralization and ALP activity. Importantly, VPC-32183 abolished the effect of BzATP on mineral deposition (Fig. 8, A and B). In contrast, the LPA receptor antagonist had only a modest effect on the BzATP-induced increase in ALP activity (Fig. 8, A and C). In addition, VPC-32183 itself had no effect on cell numbers (Fig. S3 A, available at http://www.jcb.org/cgi/content/full/jcb.200708037/DC1). In some experiments, total RNA was collected and real-time RT-PCR analysis was performed. VPC-32183 abolished the increase in expression of osterix and osteocalcin induced by BzATP (Fig. 8 D). These data indicate that BzATP-induced osteogenesis is dependent on pathways downstream of LPA receptors.

It is possible that BzATP-induced osteogenesis involves signaling pathways in addition to LPA. Activation of PLA2 leads to production of eicosanoids such as prostaglandin E2 (PGE2), which is known to stimulate bone formation in vitro and in vivo (Flanagan and Chambers, 1992; Yoshida et al., 2002). Therefore, we determined the effects of BzATP on synthesis of PGE2. After 5 min, 300 μM BzATP significantly increased PGE2 release from rat calvarial cell cultures (Fig. 9 A). 10 μM ibuprofen, which inhibits both COX-1 and -2, blocked the effects of BzATP on PGE2 synthesis. In contrast, VPC-32183 did not inhibit PGE2 production (n = 3 independent experiments; unpublished data), indicating that BzATP-induced prostaglandin synthesis does not depend on LPA receptor activation.

We next explored the role of COX in P2X7-induced osteogenesis. Rat calvarial cells were differentiated with or without 100 μM BzATP, and in the presence of 10 μM ibuprofen, 10 μM NS-398 (a selective COX-2 inhibitor), or vehicle for 14 d. Like VPC-32183, NS-398 itself had no effect on cell numbers (Fig. S3 B). Again, BzATP stimulated mineralization and ALP activity (Fig. 9 B). Similar to the actions of VPC-32183, COX inhibitors abolished the effects of BzATP on mineralization and osteocalcin expression while only slightly suppressing ALP activity (Fig. 9, C–E). Activation of P2X7 receptors did not significantly alter expression of COX-2 at 14 d (mRNA levels in BzATP-treated cells were 122 ± 5% of control; n = 3 independent experiments; P > 0.05). However, it is possible that BzATP transiently alters COX-2 expression at earlier times. Collectively, these data implicate eicosanoid signaling along with LPA in mediating P2X7-induced osteogenesis (Fig. 10).
and activates the early growth response protein Egr-1 (Pines et al., 2003). Moreover, ATP and UTP at low concentrations have been reported to inhibit bone nodule formation by rat calvarial osteoblasts (Hoebertz et al., 2002), an effect which is mediated by P2Y2 receptors and the release of pyrophosphate (Orriss et al., 2007).

The late onset of differences between the skeletons of P2rx7/H11002 and wild-type mice is consistent with a role for P2rx7 in mechanically stimulated bone remodeling rather than in development per se.

We identified functional P2X7 receptors in cells of the osteoblast lineage in situ. This finding rules out the possibility that receptor expression is induced by in vitro culture, as reported previously for P2Y2 receptors in cells from rat submandibular salivary gland (Turner et al., 1997). Functional P2X7 receptors were present in cells located on the ectocranial surface of calvariae, which undergoes active osteogenesis during cranial expansion. In vitro, P2X7 receptors are expressed in a subpopulation of calvarial cells and bone marrow stromal cells. Interestingly, calvarial cells expressing functional P2X7 receptors were associated with bone-like nodules, which is consistent with their expression in differentiated osteoblasts and with a role for these receptors in osteogenesis.

In addition to effects mediated by P2X7 receptors, nucleotides may regulate osteogenesis via interactions with other P2 receptor subtypes as well as by providing a source of Pi (which promotes mineralization) and pyrophosphate (which inhibits mineralization). Thus, effects of nucleotides on osteoblasts likely differ depending on which P2 receptor subtypes are activated. At concentrations too low to activate P2X7 receptors but sufficient to activate several other P2 receptor subtypes, ATP stimulates the proliferation of osteoblast-like cells (Shimegi, 1996; Nakamura et al., 2000) and activates the early growth response protein Egr-1 (Pines et al., 2003). Moreover, ATP and UTP at low concentrations have been reported to inhibit bone nodule formation by rat calvarial osteoblasts (Hoebertz et al., 2002), an effect which is mediated by P2Y2 receptors and the release of pyrophosphate (Orriss et al., 2007).

Figure 9. COX inhibitors suppress BzATP-enhanced mineralization in rat calvarial cell cultures. (A) Rat calvarial cells were incubated in serum-free medium for 15–18 h and then treated for 10 min at 37°C with 10 μM ibuprofen (COX inhibitor) or vehicle. 300 μM BzATP or its vehicle (control) was then added and cultures were incubated for an additional 5 min. Media were collected and levels of PGE2 assessed. Data are expressed as percentages of PGE2 levels in vehicle-treated control. *, significant effect of BzATP compared with corresponding control (P < 0.05; n = 3 independent preparations). (B) During differentiation, rat calvarial cells were treated with 10 μM ibuprofen, 10 μM NS-398 [COX-2 inhibitor], or vehicle and also with 100 μM BzATP or its vehicle (control) for 14 d. Cultures were fixed and stained for ALP activity and mineral deposition. Bar, 1 mm. (C) and (D) Ibuprofen and NS-398 abolished the effects of BzATP on mineralization (C) and moderately suppressed ALP activity (D). (E) Osteocalcin expression was quantified by real-time RTPCR. Data are expressed relative to values in vehicle-treated control. NS-398 abolished the effect of BzATP on osteocalcin expression. Data are means ± SEM (n = 3 independent preparations). **, significant effect of BzATP compared with control (P < 0.05).

Figure 10. Proposed P2X7-LPA signaling axis promoting osteogenesis. Activation of P2X7 receptors on cells of the osteoblast lineage by endogenous ATP or exogenous BzATP leads to production of LPA through a pathway involving PLD and PLA2. In addition, activation of PLA2 leads to production of COX metabolites such as prostaglandins (PG). LPA and prostaglandins then bind to their receptors on the same or neighboring cells to induce expression of osteoblast genes such as osterix and osteocalcin. Up-regulation of these genes in turn induces osteogenesis by promoting differentiation and mineralization.
Regulation of gene expression by P2X7 receptors during osteogenesis

Characterization of mice lacking genes encoding Runx2 and osterix has established the roles of these transcription factors as master regulators of osteoblast differentiation (Ducy et al., 1997; Nakashima et al., 2002). Runx2−/− mice also exhibit a defect in the differentiation of hypertrophic chondrocytes (Enomoto et al., 2000). We found that there was significant regulation in osterix, but not Runx2, mRNA in calvarial cell cultures from P2rx7−/− mice compared with the wild type. Runx2 functions upstream of osterix and can directly regulate its expression (Nishio et al., 2006). Thus, it is likely that P2X7 receptors up-regulate expression of osterix and promote osteoblast differentiation downstream of Runx2 or via effects on Runx2 activity that can be regulated by phosphorylation (Ge et al., 2007). Moreover, in P2rx7−/− calvarial cell cultures, we observed down-regulation of the gene encoding osteocalcin, which is known to be regulated by osterix (Nakashima et al., 2002).

We found that deletion of P2rx7 not only suppresses osteoblast differentiation but enhances expression of the adipocyte markers PPARγ and lipoprotein lipase. Bipotential mesenchymal cells can differentiate into cells of the osteoblast or adipocyte lineage depending on levels of osterix and PPARγ expression (Ali et al., 2005). Thus, it appears that activation of P2X7 receptors directs cells toward the osteoblast lineage. Like Runx2 and osterix in osteoblasts, Sox9 regulates chondrocyte differentiation through activation of several genes including Col2a1 (Lefebvre et al., 1997). We found that there was no significant difference in Sox9 and Col2a1 expression in calvarial cells from P2rx7−/− compared with wild-type mice at any time during differentiation. It has been shown that Sox9 in embryonic osteochondroprogenitor cells regulates both intramembranous and endochondral ossification; however, expression of Sox9 precedes that of Runx2 and osterix (Akiyama et al., 2005). Collectively, P2X7 receptors appear to regulate osteogenesis at a stage later than Sox9 induction, which is consistent with the skeletal phenotype of the P2rx7−/− mouse in which long bone length and presumably chondrocyte differentiation are unaffected (Ke et al., 2003).

The role of lipid signaling pathways in P2X7-induced osteogenesis

In the present study, we have shown directly that BzATP induces production of phosphatidic acid (via activation of PLD) and LPA (via activation of PLD and PLA2) in osteoblasts. LPA is a soluble mediator that acts on G protein–coupled receptors, five of which, LPA1–5, are currently identified in mammals (Anliker and Chun, 2004; Lee et al., 2006). LPA binds to its receptors on cells of the osteoblast lineage and subserves many functions, such as promoting proliferation, inducing migration, and regulating morphology (Grey et al., 2001; Masiello et al., 2006; Panupinthu et al., 2007).

It is possible that the role of LPA in osteogenesis has not been recognized previously because LPA is abundant in serum used to supplement media for in vitro bone formation assays. Moreover, production of LPA may explain previous reports of apparently anomalous responses to P2X7 receptor activation in other systems. For example, heterologous expression of P2X7 receptors in lymphoid and other cell types confers the ability to grow in the absence of serum (Baricordi et al., 1999; Adinolfi et al., 2005), possibly because of the production of LPA.

Activation of PLA2 is a key step in the production of LPA as well as the formation of eicosanoids. In the present study, we showed that the COX pathway is involved in P2X7-induced osteogenesis in concert with LPA receptor signaling. In keeping with our findings, bone marrow–derived osteoblasts exhibit reduced osterix expression in the absence of the gene encoding COX-2 (Zhang et al., 2002). Interestingly, mechanically induced release of PGE2 is impaired in osteoblasts from P2rx7−/− mice (Li et al., 2005). Moreover, release of ATP in response to mechanical stimulation leads to the production of PGE2 in MC3T3-E1 osteoblastic cells (Genetos et al., 2005).

Based on our pore formation and receptor expression studies, it appears that differentiated cells of the osteoblast lineage express functional P2X7 receptors. However, studies of marker gene expression indicated that these receptors regulate the differentiation of less mature cells. In this regard, LPA and eicosanoids produced in response to activation of P2X7 receptors on mature osteoblasts may act as autocrine factors on the same cells. In addition, these mediators could act as paracrine factors to stimulate the differentiation of less mature cells in the surrounding region. Collectively, we have identified two lipid signaling pathways, involving LPA and eicosanoids, underlying P2X7-induced osteogenesis.

Physiological relevance of P2X7-induced osteogenesis

ATP is released from bone cells in vitro through constitutive and inducible mechanisms (Buckley et al., 2003; Genetos et al., 2005). In P2rx7−/− mice, osteogenesis (Ke et al., 2003) and ana- bolic responses to mechanical loading (Li et al., 2005) are impaired, indicating that release of ATP into the bone extracellular fluid occurs in vivo. Our present data are consistent with release of endogenous ATP stimulating osteogenesis in vitro. In this regard, it has been shown that the differentiation of rat calvarial cells is accompanied by a fivefold increase in cytosolic ATP content at 10–14 d (Komarova et al., 2000). However, the concentration of ATP in the extracellular compartment depends upon the balance between the release of ATP and its degradation by ectonucleotidases. Therefore, it is conceivable that constitutive ATP release in vivo is insufficient to activate P2X7 receptors, whereas enhanced release arising from mechanical stimulation is sufficient to trigger P2X7 signaling.

In keeping with a role for P2X7 in mechanotransduction, differences in osteogenesis in P2rx7−/− mice are most noticeable at sites in long bones that experience large mechanical strain caused by weight bearing (Ke et al., 2003). It is known that osteogenesis on periosteal surfaces correlates with applied stress (Robling et al., 2006). In this paper, we characterized an additional defect in the P2rx7−/− mouse involving impaired suture bone growth. Tensile forces caused by intracranial pressure are thought to trigger the growth of bone at sutures (Hou et al., 2007). Therefore, it is possible that mechanical strain induces local release of ATP, which then activates P2X7 receptors on cells of osteoblast lineage, inducing osteogenesis.
In summary, we propose that the P2X7-LPA axis, together with eicosanoid signaling, promotes osteogenesis. It is well established that release of the endogenous P2X7 agonist ATP is stimulated by fluid shear and mechanical deformation of cells (Romanello et al., 2001; Genetos et al., 2005; Riddle et al., 2007). Thus, the P2X7-LPA axis likely plays a critical role in skeletal remodeling and mechanotransduction.

Materials and methods

Materials

α-MEM, heat-inactivated FBS, antibiotic solution (10,000 units/ml penicillin, 10,000 μg/ml streptomycin, and 25 μg/ml amphotericin B), PBS, TRIZOL reagent, SYTO-13, propidium iodide, HOECHST 33342, Flu-4-AM, and Pluronic F127 were obtained from Invitrogen. Nucleotides, collagenase type II, naphthol AS-MX phosphate, Fast Red B salt, ibuprofen, and LPA (1-oleoyl-snglyceryl-3-phosphate) were purchased from Sigma-Aldrich. 1-Butanol, NS-398, and ethidium bromide were obtained from EMD. BEL was obtained from Thermo Fisher Scientific. tert-Butanol was obtained from Thermo Fisher Scientific. Ar + ion laser excitation with a 500–530-nm band-pass emission filter for epi-fluorescence and a 610–670-nm band-pass emission filter for epi-fluorescence was used. Internal control reaction was performed using 18S ribosomal RNA Sequence Detection Kit (PerkinElmer). The P2X7-LPA axis likely plays a critical role in skeletal remodeling and mechanotransduction.

Animals

The P2rx7−/− mouse, generated as described previously (Sollie et al., 2001), was obtained from Pfizer. Both wild-type and P2rx7−/− mice were maintained in a mixed genetic background (129/Ola × C57BL/6 × DBA/2). Each animal was killed at an angular increment of 0.5 ° and a 360 ° rotation. Data were acquired to the x-ray source with a potential of 80 kV and a current of 0.45 mA at a rate of three frames per 2 s for each angle. X-ray images were acquired using an AlphaImager 2200 (Alpha Innotech Corporation). Magnification and brightness were standardized and 2D images were analyzed using Image Master software (GE Healthcare).

Microcomputed tomography

Skin and viscera were removed and specimens fixed in 10% formalin solution. Specimens were prepared in 3% BSA and aliquots were stored at −20°C. Nominally dailentation-free buffer contained the following: 140 mM NaCl, 5 mM KCl, 20 mM Na-Hepes, and 10 mM glucose, pH 7.35 ± 0.02, 290 ± 5 mosmol/L. For short-term experiments, we used BzATP in 200 mM Na-Hepes, and 10 mM glucose, pH 7.35 ± 0.02, 290 ± 5 mosmol/L. For long-term experiments, we used 100 μM BzATP in medium (~EC50) to minimize baseline activity in calvarial osteoblasts (Panupinthu et al., 2007). For short-term experiments, we used 100 μM BzATP in medium (~EC50) to minimize possible nonspecific effects.

Animals

The P2rx7−/− mouse, generated as described previously (Sollie et al., 2001), was obtained from Pfizer. Both wild-type and P2rx7−/− mice were maintained in a mixed genetic background (129/Ola × C57BL/6 × DBA/2) by crossbreeding of DBA/2. P2rx7−/− mice were killed at 9 mo of age. Skin and viscera were removed and specimens fixed in 10% formalin solution. Specimens were prepared in 3% BSA and aliquots were stored at −20°C. Nominally dailentation-free buffer contained the following: 140 mM NaCl, 5 mM KCl, 20 mM Na-Hepes, and 10 mM glucose, pH 7.35 ± 0.02, 290 ± 5 mosmol/L. For short-term experiments, we used BzATP in medium (~EC50) to minimize possible nonspecific effects.

Microcomputed tomography

Male and female wild-type and P2rx7−/− mice were killed at 9 mo of age. Skin and viscera were removed and specimens fixed in 10% formalin solution. Specimens were prepared in 3% BSA and aliquots were stored at −20°C. Nominally dailentation-free buffer contained the following: 140 mM NaCl, 5 mM KCl, 20 mM Na-Hepes, and 10 mM glucose, pH 7.35 ± 0.02, 290 ± 5 mosmol/L. For short-term experiments, we used BzATP in medium (~EC50) to minimize possible nonspecific effects.

BEL was obtained from BIOMOL International, L.P. [1-14C]Glycerol was obtained from PerkinElmer. VPC32183 and reference membrane lipids, including 16:0-18:1 phosphatidylcholine, 16:0 lysophosphatidylcholine, 16:0-18:1 phosphatidic acid, 16:0 LPA, 16:0-18:1 phosphatidylethanolamine, 16:0-18:1 phosphatidylglycerol, and 16:0-18:1 lysophosphatidylglycerol were obtained from Avanti Polar Lipids, Inc. Stock solutions of LPA and VPC32183 were prepared in 3% BSA and aliquots were stored at −20°C. Nominally dailentation-free buffer contained the following: 140 mM NaCl, 5 mM KCl, 20 mM Na-Hepes, and 10 mM glucose, pH 7.35 ± 0.02, 290 ± 5 mosmol/L. For short-term experiments, we used BzATP in medium (~EC50) to minimize possible nonspecific effects.

In vitro pore formation assay

Rat calvarial cells were isolated and plated in culture medium on a two-well Lab-Tek Chamber Slide (Thermo Fisher Scientific) at a density of 3 × 105 cells/cm2. Cultures were differentiated with ascorbic acid and β-glycerophosphate for 14–21 d. Some experiments were also performed using undifferentiated cells isolated from long bones of newborn rats. Pore formation assay was performed in nominally divalent cation-free buffer with BzATP or its vehicle as described in In situ pore formation assay and confocal microscopy. In vitro studies were performed using propidium iodide rather than ethidium bromide.

Cytochemical analyses of ALP activity and mineral deposition

Calvarial cell cultures were fixed with 4% formalin buffered formalin over-night at 4°C. ALP activity was revealed using a mixture of 0.25 mM naphth AS-MX phosphate and 1.25 mM Fast Red B salt in 0.1 M Tris-HCl, pH 8, for 1 h in the dark. To demonstrate mineral deposition, the same cultures were stained with 2.5% wt/vol silver nitrate solution (von Kossa staining) for 1 h with exposure to light. Images of rat calvarial cell cultures were captured using a microscope (SMZ1500; Nikon) with Plan APO objective (0.1 NA) attached to a charge-coupled device camera (CoolSNAP; Roper Scientific). Mineralized and ALP-positive areas were quantified using four fields per well. Images of murine calvarial cell cultures were captured using a scanner (Perfection 1650; Epson). Mineralized and ALP-positive areas were quantified from the entire well. Sizes of acquisition fields and color balance were standardized and 2D images were analyzed using Image Master software (Photon Technology International, 2017).

RT-PCR analyses

For real-time RT-PCR analyses, total RNA was isolated from differentiated calvarial cell cultures at 7-d intervals using TRIZOL reagent and the RNeasy Mini kit (QIAGEN). Primer and probe sequences for genes encoding Runx2 (Runx2), osterix (Sp7), bone sialoprotein (Bsp), osteocalcin (Bglap1), Sox9 (Sox9), and collagen type II (Col2a1) were designed using PrimerDesigner software (Applied Biosystems; Table S1, available at http://www.ncbi.org/cgi/content/full/pcr.200708037/DC1). Primers and probes for P2X7 (P2x7), PPARγ (Pparg), lipoprotein lipase (Lpl), and COX-2 (Pigs2) were purchased from Applied Biosystems (Gene Expression Assay). Real-time RT-PCR was performed using the ABI Prism 7900 HT Sequence Detector (PerkinElmer) with 15-μl final reaction volumes, which contained a 25-ng RNA solution, TaqMan Gene Expression Master Mix kit (Applied Biosystems), and gene-specific target primers and probes (FAM dye). Internal control reaction was performed using 18S ribosomal RNA primers and probes (VIC dye). Reverse transcription was performed at 48°C for 30 min. Amplification was performed for 40 cycles with an annealing temperature of 60°C. All samples were amplified in three parallel reactions. Data from serial dilution of total RNA were used to calculate relative quantities of transcrits of interest.

For conventional RT-PCR analysis of P2xr7 expression, total RNA was extracted from undifferentiated cultures of cells isolated from rat calvariae and long bones, as well as the UMR-106 osteoblast-like cell line (negative control). RT-PCR was performed as described previously (Dixon et al., 2004). Images of gels were acquired using an AlphaImager 2200 (Alpha Innotech Corporation) with a zoom lens (Computer 1V, 1.2 NA, CBC AMERICA Corporation).
DNA assay
To label DNA, osteoblasts were loaded with 5 μg/ml Hoechst 33342 for 30 min in culture medium at 37°C. Cells were trypsinized and fluorescence intensity of samples from each well was measured using a fluorimeter (RF-M2004; Photon Technology International) with excitation at 350 nm and emission at 450 nm.

Extraction of lipids and thin layer chromatography
Calvarial cells were isolated from newborn rats or mice (wild type and P2rx7−/−) and labeled with 1 μCi/ml [3H]glycerol in serum-free α-MEM for 18 h. Medium containing unincorporated radiolabeled was then replaced with nominally divalent cation-free buffer containing inhibitors or vehicle. After 10 min, BzATP or its vehicle (control) was added. After a further 20 min, buffer was exchanged and lipids were extracted from the cell layer (Bligh and Dyer, 1959). Extracts were dried under a stream of N2 and dissolved in chloroform together with the reference membrane lipids. Silica gel plates (K442; Whatman) were sprayed with a solution of 0.05 M magnesium acetate and 0.35 M oxalic acid. After plates were dried, samples were loaded and separated by thin layer chromatography using the following solvent system (by volume): 34:30:35:6.5 ethanol/chloroform/triethylamine/water. After chromatography, plates were sprayed with 0.1 mM rhodamine 6G and examined by confocal microscopy at room temperature using a 500–530-nm band-pass filter. Fluorescence intensity was analyzed using LSM 510 software.

Fluorescence measurement of [Ca2+]
Undifferentiated calvarial cells were plated on 35-mm glass bottom culture dishes (MatTek Corporation) at a density of 3 × 104 cells/cm2 for 24 h. Cells were loaded by incubation with 2.5 μM Fluo-4-AM and 0.1% Pluronic F127 in serum-free α-MEM for 30 min at 37°C. Cultures then were washed with serum-free medium, incubated with FPC-32183 or vehicle, and examined by confocal microscopy at room temperature using a Plan-Apochromat 40× objective (1.2 NA; Carl Zeiss, Inc.) with 488-nm Ar+ ion laser excitation. Emission wavelength was gathered using a 500–530-nm band-pass filter. Fluorescence intensity was analyzed using LSM 510 software.

PGE2 assay
Rat calvarial cells were incubated in serum-free α-MEM at 37°C for 18 h. Medium was then replaced with nominally divalent cation-free buffer containing inhibitors or vehicle for 10 min at 37°C. BzATP or its vehicle (control) was then added. After a further 5 min, buffer was collected and PGE2 levels were measured using PGE2 Express Enzyme Immunoassay kit (Cayman Chemical).

Statistical analyses
Data are shown as means ± SEM. Differences between two groups were assessed using t tests. Differences among three or more groups were evaluated by one-way analysis of variance followed by a Tukey multiple comparison test, or two-way analysis of variance followed by a Bonferroni multiple comparisons test. Differences were accepted as statistically significant at P < 0.05.

Online supplemental material
Fig. S1 shows that osteoblasts from both calvariae and long bones express P2rx7 transcripts and that P2X7 receptors on long bone cells are functional. Fig. S2 shows that BzATP does not affect phosphatidylethanolamine and choline/ethanolamine/free fatty acids in rat calvarial cell cultures. Fig. S3 shows that VPC-32183 and NS-398 do not affect osteoblast transcription and that P2X7 receptors on long bone cells are functional. Fig. S1 shows that osteoblasts from both calvariae and long bones express P2rx7 transcripts and that P2X7 receptors on long bone cells are functional.
