Sam68 regulates translation of target mRNAs in male germ cells, necessary for mouse spermatogenesis

Introduction

Mammalian spermatogenesis is a striking example of posttranscriptional regulation of gene expression (Schafer et al., 1995; Braun 1998; Walker et al., 1999; Elliott, 2003). Because de novo transcription is not always possible during germ cell differentiation, the mRNAs for several proteins involved in spermatogenesis need to be synthesized and stored well before their translation is needed. Chromatin becomes unavailable for transcription during homologous recombination in the first meiotic prophase (Turner et al., 2005). It follows a wave of intense transcription at the pachytene stage until the onset of chromatin condensation that precedes the first division (Monesi, 1964). Later, when round spermatids differentiate into elongated spermatids, the nucleus is rendered transcriptionally inactive due to extensive nuclear remodeling, replacement of histones with the highly basic protamines, and compaction of the chromatin (Sassone-Corsi, 2002). As a consequence of these processes, several mRNAs synthesized during the transcriptionally active stages of spermatogenesis are stored and protected by a profusion of ribonucleoproteins (RNPs), which preserve them until their translation begins (Geremia et al., 1977; Schafer et al., 1995; Kleene, 2001). In particular, it was found that >700 transcripts are differentially shifted from the RNPs to the polysomes in a developmentally regulated manner during spermatogenesis (Iguchi et al., 2006). However, the mechanisms and the RNA-binding proteins (RBPs) that participate to their translational control in male germ cells are still largely unknown.

Interestingly, Sam68 is associated with polyadenylated mRNAs in the cytoplasm during the meiotic divisions and in round spermatids, when it interacts with the translational machinery. We show that Sam68 is required for polysomal recruitment of specific mRNAs and for accumulation of the corresponding proteins in germ cells and in a heterologous system. These observations demonstrate a novel role for Sam68 in mRNA translation and highlight its essential requirement for the development of a functional male gamete.
Figure 1. Sam68 is required for male fertility. (A) Analysis of the fertility phenotype of Sam68+/− (n = 5) and Sam68−/− (n = 6) mice. Mice were bred for 5 mo with wild-type females of proven fertility. Females were changed each time they remained pregnant or after 2.5 mo without remaining pregnant. (B and C) Ovulation was induced in wild-type females by hormonal treatment before mating with Sam68+/+, Sam68+/− (n = 3), and Sam68−/− (n = 3) males. Mating was confirmed by observation of the vaginal plug 15 h later, and oocytes were collected from the oviducts 18 h after mating. Fertilization...
A class of RBPs that play essential roles in development is represented by the signal transduction and activation of RNA (STAR) family (Lukong and Richard, 2003; Volk et al., 2008). A prototype STAR protein, the Caenorhabditis elegans GLD-1, functions as translational regulator during female gametogenesis (Francis, et al., 1995; Lee and Schedl, 2001). The mammalian STAR protein QUAKING (QKI) has been shown to regulate mRNA stability, mRNA export, and pre-mRNA splicing (Chenard and Richard 2008; Volk et al., 2008). Another mammalian STAR protein, Src-associated substrate in mitosis of 68 kD (Sam68 or KHDRBS1; Fumagalli et al., 1994; Taylor and Shalloway, 1994), plays a role in several aspects of RNA metabolism, from alternative splicing (Matter et al., 2002, Cheng and Sharp, 2006; Paronetto, et al., 2007; Chawla et al., 2009) to nuclear export (Li et al., 2002) and cytoplasmic utilization of viral mRNAs (Coyle, et al., 2003). Moreover, Sam68 was found associated to the polysomes in depolarizing neurons and meiotic germ cells (Grange et al., 2004; Paronetto et al., 2006). Src-related kinases and mitogen-activated kinases phosphorylate Sam68 and regulate its RNA-binding affinity (Wang et al., 1995; Tisserant and König, 2008) and its activity in alternative splicing (Matter et al., 2002; Paronetto, et al., 2007), which indicates that Sam68 is able to integrate intracellular signals and RNA processing. Mice with knockout for the Sam68 gene are protected from age-related bone loss and mammary gland tumors, revealing a function of this protein in mesenchymal stem cell differentiation (Richard, et al., 2005), tumorigenesis, and metastasis (Lukong et al., 2008; Richard et al., 2008). Nevertheless, whether or not the defects observed in Sam68−/− mice are caused by deregulation of specific cellular mRNAs in the cell remains unknown.

In this paper, we show that male Sam68 knockout mice are infertile due to aberrant differentiation of round spermatids into mature spermatozoa. We have identified a subset of testicular transcripts that are affected by Sam68 ablation and found an enrichment in mRNAs encoding proteins involved in cell proliferation and survival. Several of these mRNAs are bound by Sam68 in germ cells. Moreover, we provide evidence that upon meiotic divisions, Sam68 associates with the translation initiation complex and regulates polysomal loading and translation of the mRNAs encoding SPAG16, a cytoskeletal protein required for sperm motility and fertility; NEDD1, a centrosomal protein required for microtubule organization; and SPDYA, a cell cycle regulator. Our findings suggest that Sam68 loss of function leads to male infertility by restricting translation of a selected group of mRNA transcripts.

Results

Sam68 is required for male fertility

Sam68 expression is strongly expressed in meiotic and postmeiotic male germ cells of the testis, which suggests a role in spermatogenesis (Fig. S1). To investigate whether Sam68 is required for male fertility, we analyzed the reproductive phenotype of Sam68−/− mice. Crosses with wild-type females of proven fertility indicated that Sam68−/− males did not produce offspring, whereas Sam68+/− males were fertile (Fig. 1 A). To rule out behavioral defects affecting mating, Sam68+/+, Sam68+/−, or Sam68−/− males were crossed with hormonally primed wild-type females, and mating was scored by observation of the vaginal plug. Although Sam68−/− mice formed plugs, they were unable to fertilize wild-type oocytes, as shown by the lack of pronuclei (Fig. 1, B and C), whereas their littersmates were fertile in this assay. These findings show that Sam68 expression is required for male fertility and that the infertile phenotype of Sam68−/− males is not due to altered mating behavior.

Sam68 expression is required for the correct progression of spermatogenesis

Testicular atrophy is a common feature of infertile knockout male mice. Although Sam68 depletion did not cause general testicular atrophy, the testis/body weight ratio was significantly lower in Sam68−/− as compared with their littermate controls (Fig. S2, A–C). Serum testosterone levels, although very variable from animal to animal, were not significantly different in Sam68−/− mice (Fig. S2, D), which indicates that the smaller testis size and male infertility were not caused by decreased androgen levels. The seminiferous tubules of adult Sam68−/− mice had a thinner epithelium than the wild-type tubules due to a strong reduction in postmeiotic haploid cells, which affected both the early round spermatids and the more differentiated elongated spermatids (Fig. 1 D). A developmental analysis of testicular histology revealed that the defects in spermatogenesis of Sam68−/− mice first appeared at the time when the bulk of meiotic divisions occurs (25 days postpartum [dpp] in Fig. S3). The reduction in postmeiotic cells was maintained throughout the first spermatogenic wave (45 dpp in Fig. S3). In contrast, no major defects were apparent at 16 dpp, before the onset of the meiotic divisions (Fig. S3). Analysis of DNA content in purified germ cells by flow cytometry quantified the reduction in haploid spermatids of Sam68−/− mice to 45% in juvenile (Fig. 1, E and F) and 29% in adult testes (Fig. S2 E).

A aberrant divisions of meiotic cells were observed in Sam68−/− testes (Fig. S2, F and G). Histological examination revealed the presence of incompletely divided germ cells, containing two or three nuclei of postmeiotic round spermatids that were prematurely shed in the lumen of the tubule (Fig. S2 G). Moreover, TUNEL assays showed the presence of a larger number of dying germ cells in Sam68−/− testes, especially at 25 dpp, when most tubules contain meiotically dividing spermatocytes or early round spermatids (Fig. 2 A). Flow cytometry showed that increased apoptosis affected all germ cells in 25-dpp animals (Fig. 2, B and C).
Figure 2. Ablation of Sam68 increases germ cell apoptosis and impairs spermiogenesis. (A) TUNEL staining of testicular sections from wild-type or knockout 25 dpp (top) and adult (bottom) mice. Sam68<sup>−/−</sup> testes show increased apoptosis. Nuclear brown signal indicates apoptotic cells. In adult testis, apoptotic cells mainly reside in the luminal pole of the tubule where the haploid cells are localized. Bars, 100 µm. (B) Flow cytometry analysis of TUNEL-positive germ cells. Staining with propidium iodine (x axis) allowed us to identify haploid (1C), diploid (2C), or tetraploid (4C) germ cells. TUNEL staining on January 1, 2018 jcb.rupress.org Downloaded from
Electron microscopy confirmed the severe defects in spermiogenesis in Sam68<sup>−/−</sup> tests. We observed several frequent abnormalities, ranging from aberrant nuclear divisions (Fig. 2 D, a), elongating spermatids with two flagella (Fig. 2 D, b, arrows), elongated spermatids with two nuclei (Fig. 2 D, c), and delayed spermatid differentiation, with step 9–10 spermatids observed in tubules at stage XII (Fig. 2 D, d, arrow). Nevertheless, although they were strongly reduced in number (Fig. 2 E), few mature spermatozoa were found in the epididymis of approximately half of the Sam68<sup>−/−</sup> mice analyzed (n = 20). Most of the spermatozoa produced by these Sam68<sup>−/−</sup> mice were abnormally shaped and immotile. Some spermatozoa displayed motility but the majority lost their flagellum shortly after their release in fertilization medium (Video 1). Moreover, the few Sam68<sup>−/−</sup> spermatozoa that maintained reduced motility in culture (Video 2) were completely infertile even under in vitro fertilization conditions (Fig. S2, H and I). These results demonstrate that Sam68 is required for production of male haploid cells and spermiogenesis.

**Sam68 ablation affects the expression of a selected number of mRNAs in mouse testis**

Although Sam68 is an RBP, it is currently unknown whether its function in vivo requires modulation of specific mRNAs. To investigate this issue, we compared the expression of mRNAs in testes from wild-type and knockout adult mice using the Affymetrix gene expression chips. We found that 294 and 124 targets were significantly (P < 0.05) down-regulated and up-regulated in Sam68<sup>−/−</sup> -tests (Fig. 3 A; Tables S1 and S2), respectively. Analysis through the Ingenuity Pathway Analysis (IPA) Systems revealed that the top four functional categories among the down-regulated targets were cell cycle (P = 1.09 × 10<sup>−4</sup>–4.12 × 10<sup>−2</sup>), cell death (P = 1.09 × 10<sup>−4</sup>–4.12 × 10<sup>−2</sup>), cancer (P = 3.24 × 10<sup>−4</sup>–4.12 × 10<sup>−2</sup>), and cell-to-cell signaling and interaction (P = 3.24 × 10<sup>−4</sup>–3.11 × 10<sup>−2</sup>; Fig. 3 B; Tables S3 and S4). Regarding the up-regulated targets, the top four functional categories were cell cycle (P = 5.43 × 10<sup>−3</sup>–4.97 × 10<sup>−2</sup>), connective tissue development and function (P = 5.43 × 10<sup>−4</sup>–4.86 × 10<sup>−2</sup>), cell morphology (P = 7.93 × 10<sup>−4</sup>–3.15 × 10<sup>−2</sup>), and nervous system development and function (P = 7.93 × 10<sup>−4</sup>–4.52 × 10<sup>−2</sup>; Fig. 3 B and Tables S5 and S6). Notably, the highly significant changes in expression of genes involved in cell cycle and cell death pathways might account for the defects in meiotic divisions and the increased apoptosis observed in Sam68<sup>−/−</sup> tests. The microarray data were confirmed on 11 mRNA targets by real-time PCR (Fig. 3 C). The chosen targets included one up-regulated transcript, Riken 4931428L18, and 10 down-regulated transcripts. Among these, we chose those encoding for NEDD1, a centrosomal protein that is required for microtubule organization (Haren et al., 2006); SPDYA, a cell cycle regulator involved in oocyte meiotic maturation (Gastwirt et al., 2007); and SPAG16, a component of the sperm axoneme whose deficiency causes reduced spermatozoa motility and male infertility (Zhang et al., 2006). Actually, a deficiency in SPAG16 could be sufficient to contribute to the Sam68<sup>−/−</sup> infertility phenotype. The haploid marker Prm2, encoding for protamine 2, was unaffected in the Sam68<sup>−/−</sup> knockout tests.

To test the possibility that Sam68 is associated with polyadenylated mRNAs in pachyten spermocytes, we performed an RNP capture assay with oligo (dT)-cellulose to capture polyA mRNAs and associated proteins (Grivina et al., 2006). Under these conditions, Sam68 was efficiently retained by the oligo (dT)-cellulose, and this interaction was strongly impaired when spermatocyte cell extracts were treated with RNase A (Fig. 4 A), or when oligo (dT)-cellulose was preincubated with excess polyA but not polyC (Fig. 4 C). A similar result was obtained for the polyA-binding protein PABP1, which was used as the positive control of the experiment. These results indicate that Sam68 specifically interacts with polyadenylated RNA in mouse spermatocytes. Next, we asked whether the affected mRNAs are direct targets of Sam68 by coimmunoprecipitation experiments. In line with this hypothesis, we observed that all the mRNA targets tested specifically associated with Sam68 in RNP-immunoprecipitation experiments (Fig. 4 D). In contrast, Muc3 and Gapdh mRNAs, which were not affected by Sam68 ablation, were not associated with the protein. Sam68 was immunoprecipitated by the specific antibody but not by control IgGs (Fig. 4 E). These results suggest that Sam68 directly regulates the expression of its mRNA targets in germ cells.

**Sam68 associates with polyA mRNA engaged in translation**

The major defects observed in Sam68<sup>−/−</sup> tests affected postmeiotic haploid cells. Interestingly, Sam68 localized in the cytoplasm in secondary spermatocytes (Figs. 5 A and S1) and some round spermatids (Fig. 5 B), which suggests a role in translational control. Translational regulation in eukaryotes is frequently exerted at the initiation step (Richter and Sonenberg, 2005), which normally depends on the m7GpppN<sub>5</sub>′ cap structure of the mRNA. The mRNA 5′ cap recruits the 4OS ribosome subunit via interaction with the cap-binding protein eIF4E and the scaffold protein eIF4G (Hay and Sonenberg, 2004; Richter and Sonenberg, 2005). These steps are assisted by additional RBPs, many of which are highly or uniquely expressed in germ cells (Venables and Eperon, 1999; Elliott, 2003; Kuersten and Goodwin, 2003; Lasko et al., 2005). To test whether Sam68 is able to interact with the translation initiation complex eIF4F, we incubated spermatoocyte extracts with m7GTP-Sepharose beads. We found that Sam68 specifically bound the m7GTP-Sepharose in pachytene spermatocytes, and
that this interaction was strongly increased in extracts enriched in secondary spermatocytes (Fig. 5 C). Equal amounts of the mRNA 5' cap-binding protein eIF4E and of eIF4G were pulled down in the two cell extracts. Remarkably, in somatic HEK293 cells, in which Sam68 is exclusively nuclear (Paronetto et al., 2007), no association with the eIF4F complex was observed (Fig. 5 D). These results demonstrate that Sam68 interacts with the translation initiation complex in male germ cells.

Sam68 associates with polysomes in secondary spermatocytes, and this cosedimentation in the “heavy” fractions required polysome integrity, as it was disrupted in the presence of EDTA (Fig. 5 E). A similar redistribution toward the RNP fractions was observed for PABP1 (Fig. 5 E), which is known to remain associated to mRNAs during translation (Collier et al., 2005). Thus, we next asked whether Sam68 was also bound to mRNAs engaged in translation on the polysomes. RNP-capture assays using the polysomal pool (1–5) of the fractionation of secondary spermatocyte-enriched extracts showed that polysome-associated Sam68 was captured by the oligo (dT)–cellulose, and that this interaction was counteracted by excess synthetic polyA RNA in the same manner as with PABP1 (Fig. 5 F). In line with the association of Sam68 with polyadenylated mRNA complexes in...
germ cells, we found that Sam68 specifically associated with PABP1 in coimmunoprecipitation experiments using spermatocyte cell extracts (Fig. 5 G). These experiments suggest that Sam68 remains associated with polyadenylated mRNAs engaged in translation in male germ cells.

**Sam68 is required for translation of Spag16, Nedd1, and Spdya mRNAs**

To investigate whether Sam68 is required for polysomal recruitment of target mRNAs, we performed polysomal gradients using the germ cell population enriched in secondary spermatoctyes and early round spermatids. RNA was purified from each of the 10 fractions of the gradients, and semiquantitative RT-PCR analyses were performed to determine the distribution of Sam68 target mRNAs (Fig. 6 A). Ablation of Sam68 did not affect the profile of polysomal gradients (unpublished data), demonstrating that it did not impair overall translation. Nevertheless, we observed that polysomal recruitment of Spag16, Nedd1, and Spdya mRNAs was decreased (Fig. 6 A). The distribution of these mRNAs in Sam68+/− cells formed two peaks, a larger peak in the RNP fractions and a smaller peak in the translationally active polysomal fractions (Fig. 6 A). Remarkably, only the polysomal peak was reduced in Sam68−/− cells. In contrast, Gapdh mRNA was equally distributed in sucrose gradients from Sam68+/− and Sam68−/− cells. This specific decrease in polysomal recruitment of Spag16, Nedd1, and Spdya mRNAs in Sam68−/− cells was confirmed by real-time PCR on polysomal and RNP fractions (Fig. 6 B). However, polysomal recruitment of the haploid cell–specific mRNAs Tpn2 and Prm2 was not impaired (Fig. 6 B), which indicates that the effects observed were not caused by alterations in the germ cell population. Consistent with the mRNA results, we found that SPAG16, NEDD1, and SPDYA proteins were strongly also reduced at the protein level in germ cells purified from Sam68−/− testes (Fig. 6, C and D). These results show that Sam68 is required for translation of specific target mRNAs during male germ cell differentiation.

**Accumulation of SPAG16 and SPDYA proteins during the meiotic divisions requires Sam68**

To determine whether the cytoplasmic translocation of Sam68 during the meiotic divisions of mouse spermatocytes favored translation of target mRNAs, we treated primary spermatocytes in culture with okadaic acid (OA). This serine/threonine phosphatase inhibitor triggers entry of pachytene spermatocytes into meiotic divisions (Wiltshire et al., 1995; Sette et al., 1999), which was visualized by staining with anti-phosphoH3 (Fig. S4 A). Interestingly, Sam68 translocated to the cytoplasm and associated with polysomes after brief treatment with OA (Fig. S4, B and C), and this coincided with its phosphorylation (Fig. 7 C), which is mediated by ERK1/2 (Paronetto et al., 2006). Moreover, we found that OA treatment stimulated the association of Sam68 with the eIF4F complex (Fig. 7 A). The effect was specific because association of eIF4G with eIF4E was instead decreased by OA treatment, probably due to induction of G2–M progression of primary spermatocytes and the general decrease in cap-dependent translation in cells approaching the metaphase.

---

**Figure 4. Sam68 associates with selected polyadenylated mRNAs in mouse spermatocytes.** (A) RNP capture assay using oligo (dT)–cellulose beads and pachytene spermatocyte extracts in the presence or absence of RNase A. Proteins bound to the beads were analyzed by Western blotting with the anti-Sam68 antibody. (B) The same samples were separated by SDS–PAGE and detected by Silver staining. Molecular weight markers were loaded in the first lane. Silver staining of the gel shows that, although the pattern of bands changes, several proteins were bound to the oligo (dT) beads either in the absence or presence of RNase treatment, and that overall degradation of the sample did not occur under these conditions. (C) RNP capture assay of pachytene spermatocyte extracts were performed using oligo (dT)–cellulose beads left untreated (Ctrl) or pre-absorbed for 15 min with excess synthetic polyA or polyC RNA. Proteins bound to the beads were analyzed by Western blotting with the anti-Sam68 and the anti-PABP1 antibodies. (D) RT-PCR analysis of the enrichment in target mRNAs after co-immunoprecipitation with Sam68 from isolated wild-type germ cells. Two mRNAs that resulted in unchanged Sam68−/− tests, Gapdh and Muc3, were used as negative controls in the same experiment. (E) Western blot analysis of the quality of the control and anti-Sam68 (α-Sam68) immunoprecipitation experiments used for the RT-PCR analysis illustrated in D.
Figure 5. Cytoplasmic Sam68 associates with polyadenylated mRNAs and the translational machinery in germ cells. [A and B] Immunofluorescence analysis of germ cell populations enriched in secondary spermatocytes (A) or round spermatids (B) demonstrates that Sam68 is frequently localized in the cytoplasm in these cells. Representative examples of cytoplasmic localization are indicated by arrows. Bars, 10 μm. (C and D) Pull-down assay using the 5'-cap analogue m7GTP-Sepharose beads (M7GTP) to isolate the translation initiation complex from male germ cells (C) or HEK293 cells (D). Control pull-down assays were performed using Sepharose beads (sepharose). The panels show Western blot analysis of the Sam68, eIF4G, and eIF4E proteins in the input and bound in the pull-down assays using pachytene spermatocyte [s. cytes] extracts or extracts from a population enriched in secondary spermatocytes (II s. cytes) [C]. Bottom panels show densitometric analysis of the pull-down assays. Data are represented as ratios between Sam68 and eIF4E or eIF4G and eIF4E band intensities. (E) Absorbance profile (OD = 254 nm) of sucrose gradient sedimentation of cell extracts from a population enriched in secondary spermatocytes. Extracts were either untreated (control) or treated with EDTA. The gradients were collected in 10 fractions, starting from the bottom heavy fractions, and the bottom panels show the Western blot analysis of Sam68 and PABP1 distribution in each fraction of the gradient. [F] RNP capture assay
(Pyronnet et al., 2001). To test whether this increased association with the eIF4F complex stimulated the translation of Sam68-targeted mRNAs, we analyzed SPAG16 and SPDYA protein levels, whose expression was increased in postmeiotic germ cells (Fig. 7 B). OA treatment of spermatocytes induced a time-dependent accumulation of SPAG16 and SPDYA proteins in Sam68+/− primary spermatocytes (Fig. 7 C) concomitantly with increased phosphorylation of Sam68, as indicated by the shift in molecular weight (Matter et al., 2002; Paronetto et al., 2006), and with its association with polysomes (Fig. S4 C). Densitometric analysis using tubulin as an internal standard showed that SPAG16 levels almost doubled and SPDYA sharply accumulated by 6 h of treatment (Fig. 7 C). Remarkably, this accumulation was almost completely suppressed in knockout spermatocytes, demonstrating that translation of these proteins during the meiotic divisions requires Sam68. The increases in protein levels were not caused by enhanced stabilization or cytoplasmic export of the mRNAs, because similar levels of Spag16 and Spdyα transcripts were detected in cytoplasmic extracts during the time course of the experiment (Fig. 7 D).

To determine whether Sam68 directly enhanced translation of a target transcript, we transfected HEK293 cells with Sam68 and a luciferase reporter construct with or without the Spag16 3′ untranslated region (UTR; Fig. 8 B). Although Sam68 was exclusively localized in the nuclei of HEK293 cells, coexpression of a constitutively active form of RAS (RASL61Q) induced its cytoplasmic translocation and association with polysomes (Fig. 8 A), which correlated with activation of ERK1/2, as in germ cells (Paronetto et al., 2006). Under these conditions, Sam68 strongly enhanced expression of luciferase only in the presence of Spag16 3′ UTR. Moreover, the effect relied on extracellular signal-regulated kinase (ERK)-dependent phosphorylation, because a Sam68 mutant in which the phosphorylation sites were substituted (Matter et al., 2002) was unable to induce luciferase expression (Fig. 8 B). To determine whether the increased expression was caused by enhanced polysomal loading of the reporter mRNA, we isolated polysomal and RNP-associated mRNAs from these samples. As shown in Fig. 8 C, although the total cytoplasmic levels of luciferase mRNA were similar, expression of wild-type Sam68 increased polysomal recruitment of the reporter mRNA, whereas the phosphorylation mutant was inefficient. These data indicate that phosphorylation of Sam68 by ERKs stimulates translation of target mRNAs.

**Discussion**

Posttranscriptional regulation of gene expression is essential for the progression of spermatogenesis. A large number of mRNAs need to be accumulated during the transcriptionally active stages of germ cell differentiation and translated later on to account for the lack of transcription that occurs during homologous recombination and sperm differentiation (Kleene, 2001). RBPs are highly expressed in germ cells and likely account for this posttranscriptional regulation. The results presented herein demonstrate that the RBP Sam68 is absolutely required for male fertility and for the correct progression of spermatogenesis. The defects in germ cell differentiation were accompanied by increased apoptosis and a large reduction in haploid spermatids, which failed to differentiate into correctly shaped and fully motile spermatozoa.

The defective spermatogenesis observed in Sam68−/− mice is unlikely to be caused by androgen imbalance, as testosterone levels in the serum were normal, and a comparison of the mRNAs altered in Sam68−/− testis with those affected by deletion of the androgen receptor (Gene Expression Omnibus profiles found at http://www.ncbi.nlm.nih.gov) revealed no overlap (unpublished data). Our microarray analyses identified the first mRNAs affected by Sam68 ablation in a physiological setting. The changes in mRNA expression were not caused by the altered germ cell population (i.e., a decrease in haploid cells) because transcripts for well-defined markers of postmeiotic differentiation, such as those encoding protamine 2 and transition protein 2, were not altered in Sam68−/− testes. Remarkably, the top represented categories among the mRNA down-regulated in Sam68−/− testes were cell cycle and cell death. Because the first obvious defect in spermatogenesis appears at the time when the meiotic divisions occur and correlate with increased apoptosis, our analyses suggest that these phenotypes might be due to the lower levels of expression of several genes involved in these processes. We also found an enrichment of genes involved in cancer, in line with the recently discovered role of Sam68 in prostate cancer (Busà et al., 2007), breast cancer (Richard et al., 2008), and mixed lineage leukaemia (MLL; Cheung et al., 2007). Thus, our microarray data provide a first list of genes potentially involved in the function of Sam68 in cancer cells. Moreover, the identification of mRNAs physiologically affected by Sam68 in testis might also provide valuable information for transcripts regulated by this RBP in other tissues in which its ablation caused a phenotype, such as bone and brain (Richard et al., 2005; Lukong et al., 2008; Chawla et al., 2009).

Although we have investigated the regulation of mRNAs down-regulated in the Sam68 knockout testis, other transcripts were up-regulated. The mechanism leading to these increased levels is likely different from the translational regulation of selected targets described herein. Sam68 is nuclear in premeiotic germ cells, and it is possible that nuclear events are causing the observed up-regulation. For instance, Sam68 might stabilize target transcripts during their storage in the nucleus of meiotic cells. Alternatively, because Sam68 was found to repress viral and cellular promoters in somatic cells (Lukong and Richard, 2003), it is possible that some of the observed up-regulations are caused by the relief of such transcriptional inhibitory function of the protein.

Our results suggest that Sam68 is implicated in the regulation of translation of its target mRNAs in germ cells. First, we observed that Sam68 associates with mRNAs that are...
Figure 6. Sam68 enhances translation of Spag16, Nedd1, and Spdya mRNAs in germ cells. (A) RT-PCR analysis of the distribution of Spag16, Nedd1, Spdya, or Gapdh mRNAs in the fractions of the sucrose gradients derived from sucrose gradient fractionation of germ cell extracts from Sam68+/− or Sam68−/− mice. Densitometric analysis of the signal in each fraction was performed, and the results were represented as the percentage of total signal in all fractions in the bottom panels. (B) Quantitative real-time PCR analysis of Spag16, Nedd1, Spdya, Tpn2, and Prm2 mRNA levels in the polysomal (1–5) and RNP (8–10) fractions. Gapdh mRNA was used as an internal standard for the real-time PCR analysis. (C) Western blot analysis of Sam68, SPAG16, NEDD1, and SPDYA proteins in germ cells isolated from Sam68+/− or Sam68−/− testes. ERK2 was used as a loading control. (D) Immunofluorescence analysis of SPAG16 and NEDD1 proteins in germ cells isolated from Sam68+/− or Sam68−/− testes. Hoechst costaining was performed to distinguish pachytene spermatocytes (Pc) from round spermatids (Spt). Bars, 10 µm.
down-regulated in the knockout testis, which suggests that these represent its mRNA targets in germ cells. Moreover, we provide strong evidence that Sam68 interacts with the translational machinery in germ cells and favors translation of specific mRNAs. Sam68 binds to the translation initiation complex eIF4F and remains associated with polyadenylated mRNAs in the polysomal fraction, which strongly suggests its stable interaction with mRNAs engaged in translation. In line with this hypothesis, we demonstrate that Sam68 is required for efficient polysomal loading of three target mRNAs (*Spdy*, *Nedd1*, and *Spag16*) and that the corresponding proteins are not accumulated in *Sam68*−/− germ cells undergoing meiotic divisions or early spermatid differentiation. The effect on translation appears direct because it can be recapitulated in a heterologous system by adding the 3′ UTR region of a Sam68 target mRNA to the luciferase reporter gene. Remarkably, Sam68 function requires ERK-dependent phosphorylation both for the association with polysomes and the enhancement of luciferase mRNA translation, similar to what was observed in meiotic germ cells. Thus, our results highlight a novel role of Sam68 in translational regulation and indicate that the binding of Sam68 to its target mRNAs in the cytoplasm favors their translation during the meiotic progression of mouse spermatocytes (Fig. 9). Remarkably, SPAG16 deficiency leads to defects in sperm motility and male infertility (Zhang et al., 2006), which closely resembles the phenotype of Sam68 knockout mice. These observations suggest that the strong reduction in
SPAG16 translation observed in Sam68−/− germ cells contributes to the infertility of the knockout mice and provides functional support for the role of Sam68 in the cytoplasm of male germ cells. A role for Sam68 in mRNA translation might also be envisioned in biological contexts in which Sam68 translocates to the cytoplasm, such as in the course of viral infections (McBride et al., 1996), when it favors cytoplasmic utilization of viral mRNAs (Coyle et al., 2003), or in response to depolarization of neurons (Ben Fredj et al., 2004).

The role of Sam68 in RNA biogenesis has been recently unraveled. This RBP can strongly modulate the choice of alternative exons for the CD44, Sgce, and BCL-x pre-mRNA (Matter et al., 2002; Cheng and Sharp, 2006; Paronetto et al., 2007; Chawla et al., 2009). Alternative splicing is tightly connected to transcription...
For TUNEL analyses, testes were fixed in 4% paraformaldehyde in PBS for 12 h at 4°C. Immunohistochemical staining was performed on 5µm-thick sections using the In Situ Cell Death Detection kit (Roche) according to manufacturer’s instructions. For transmission electron microscopy, samples were fixed in 2.5% glutaraldehyde in 0.1 M cacodylate buffer, postfixed in 1% OsO4, then dehydrated in ethanol and embedded in epon. Semithin sections were stained in toluidine blue, and thin sections were conventionally contrasted with uranyl acetate and lead hydroxide. Thin sections were examined and photographed in an electron microscope (Hitachi 7000; Hitachi).

Analyses of the fertility of Sam68+/− male mice

Sam68+/− (n = 5) and Sam68−/− (n = 6) mice were bred for 5 mo with wild-type females of proven fertility. Females were changed each time they remained pregnant or after 2.5 mo without remaining pregnant. To obtain fertilized oocytes, 6–7-wk-old B6D2F1 female mice (Charles River Laboratories) were hormonally primed by injecting 5 IU of pregnant mare’s serum gonadotropin (PMSG; Intervet), and, after 46–48 h, 5 IU human chorionic gonadotropin (hCG; Intervet). Then Sam68+/+, Sam68−/+, or Sam68−/− males were added to the cage. Mating was scored 16 h later by monitoring the vaginal plugs. Oocytes and embryos were collected in freshly prepared M2 medium (Hogan et al., 1994) and scored for the presence of pronuclei as described previously (Sette et al., 2002). In vitro fertilization was performed using oocytes collected from hormonally primed B6D2F1 female mice and spermatozoa collected from Sam68+/+, Sam68+/−, or Sam68−/− males as described previously (Hogan et al., 1994). Statistical analyses were performed using the t test and the analysis of variance (ANOVA) test in all the experiments.

Cell isolation, culture, and treatments

Testes from 20–60-d-old CD1 mice (Charles River Laboratories) were used to obtain pachytene spermatocytes, secondary spermatocytes, and round spermatids by elutriation technique as described previously (Sette et al., 2002). In vitro fertilization was performed using oocytes collected from hormonally primed B6D2F1 female mice and spermatozoa collected from Sam68+/+, Sam68+/−, or Sam68−/− males as described previously (Hogan et al., 1994). Statistical analyses were performed using the t test and the analysis of variance (ANOVA) test in all the experiments.

Materials and methods

Analyses of Sam68+/− mice

The Sam68 colony was maintained by intercrossing Sam68+/− mice. Genotyping of the mice was performed as described previously (Richard et al., 2003). For hematoxylin and eosin staining, testes were fixed in bouin’s solution for 2 h, embedded in paraffin, and sectioned using standard protocols. For TUNEL analyses, testes were fixed in 4% paraformaldehyde in PBS for

Figure 9. Schematic model of the role of Sam68 in male germ cells. Upon meiotic divisions, Sam68 is released in the cytoplasm and enhances translation of mRNAs bound to it, such as those encoding for SPAG16 and SPDYA proteins. Insets show the localization of Sam68 detected by immunohistochemistry in primary and secondary spermatocytes.
RT-PCR analysis
RNA polynomial fractions were used for RT-PCR using MMIV reverse transcriptase (Invitrogen) according to manufacturer’s instructions. 10% of the reverse-transcription reaction was used as template. Quantitative real-time PCR on total, RNP, and polynomial RNAs were performed in triplicate using iQ Sybr-groen Supermix (Bio-Rad Laboratories) according to manufacturer’s instructions, as described previously (Bianchi et al., 2008). Gapdh was used to obtain the ΔΔCT values for the calculation of fold increases.

Microarray analysis
Total testis RNA from adult Sam68+/+ (n = 3) and Sam68−/− (n = 3) mice was extracted using TRIzol reagent (Invitrogen), followed by clean up on RNeasy mini/midi columns (RNeasy Mini/Midi, Qiagen). All mice were used to minimize differences in haploid cell population in juvenile animals. Approximately 2% of the genes expressed in tests were affected by Sam68 ablation. Biotin-labeled cRNA targets were synthesized starting from 5 µg of total RNA according to the Affymetrix protocol (Rossi et al., 2008). The Sam68 ablation. Biotin-labeled cRNA targets were synthesized starting from 5 µg of total RNA according to the Affymetrix protocol (Rossi et al., 2008). The size and the quality of RNA targets was checked by agarose gel electrophoresis before and after fragmentation. Targets were diluted in hybridization buffer and hybridized to GeneChipMOE430 version 2.0 arrays (Affymetrix) as described previously (Paronetto et al., 2006). For RT-PCR or microarray analysis.

Polysome–RNP fractionation by sucrose gradients
Isolated germ cells were homogenized in lysis buffer (100 mM NaCl, 10 mM MgCl2, 30 mM Tris-HCl, 1 mM DTT, and protease inhibitor cocktail [Sigma-Aldrich]) and 40 U/ml RNase OUT (Invitrogen) supplemented with 0.5% Triton X-100. 10 min of incubation on ice, the lysates were centrifuged for 10 min at 12,000 g at 4°C. The supernatants were separated on 15–50% (w/v) sucrose gradients, and proteins and RNA were collected in 10 fractions as described previously (Paronetto et al., 2006). For EDTA-treated samples, MgCl2 in the buffers was replaced with 20 mM EDTA. The incubation was performed for 15 min at room temperature and stopped by adding 3 mM EGTA.

7-methyl-GTP-Sepharose pull-down assay
For the isolation of elf4E and associated proteins, cells were lysed in buffer containing 50 mM Heps, pH 7.4, 75 mM NaCl, 10 mM MgCl2, 1 mM DTT, 8 mM EGTA, 10 mM β-glycerophosphate, 0.5 mM NaVO3, 0.5% Triton X-100, and protease inhibitor cocktail (Sigma-Aldrich). Cell extracts were incubated for 10 min on ice and centrifuged at 12,000 g for 10 min at 4°C. The supernatants were precleared for 1 h on 7-methyl-GTP-Sepharose or control Sepharose (GE Healthcare) under constant shaking. Beads were washed three times with lysis buffer, and absorbed proteins were eluted in SDS-PAGE sample buffer.

Western blot analysis
Western blot analyses were performed as described previously (Sette et al., 2002). The following primary antibodies (1:1,000 dilution) were used: rabbit anti-Sam68 and rabbit anti-Erk2 (Santa Cruz Biotechnology, Inc.); rabbit anti-phosphoERKs, anti-elf4E, and elf4G (Cell Signaling Technology); rabbit anti-SpAg16 (provided by J.F. Strauss, Virginia Commonwealth University, Richmond, VA; Zhang et al., 2006), mouse anti-tubulin, and rabbit anti-actin (Sigma-Aldrich); rabbit anti-SPDY1 (EMD); and rabbit anti-NEDD1 and rabbit anti-PABP1 (Abcam). Immunostained bands were detected by the chemiluminescent method (Santa Cruz Biotechnology, Inc.). Densitometric analysis was performed using the ImageQuant 5.0 software (GE Healthcare) and normalized for the tubulin or elf4E staining.

Immunofluorescence analysis
Mouse germ cells were fixed in 4% paraformaldehyde and washed three times with PBS. Cells were permeabilized with 0.1% Triton X-100 for 7 min and then incubated for 1 h at 0.5% BSA. Cells were washed three times with PBS and incubated for 2 h at room temperature with antibodies against Sam68 (1:1,000), phospho-H3 (1:1,000, Millipore), SPAG16 (1:200), or NEDD1 (1:200) followed by 1 h of incubation with cy3-conjugated anti-rabbit IgG (Alexa Fluor) or FITC-conjugated anti-rabbit IgG (Alexa Fluor). After washes, slides were mounted with Mowiol reagent (EMD) and analyzed by microscopy using an inverted microscope (DM6000B; Leica).

Image acquisition and manipulation
Images were taken from a fluorescent microscope (Axiostkop; Carl Zeiss, Inc.) using a Pan-Neufluor 40×/0.75 objective lens, and from an inverted microscope (DM6000B; Leica) using a Pan-Neufluor 40×/0.75 objective lens. Images were acquired at room temperature using an RT slider camera (Diagnostic Instruments) and the IAS2000 software [Biosistem 82] or Uf software (Leica). Images were acquired and多少钱?? software (Adobe) was used for composing the panels.

Online supplemental material
Fig. S1 shows stage-specific expression of Sam68 in mouse testis. Fig. S2 shows tests and body weight, testostere levels, and apoptosis analysis in wild-type, heterozygote, and knockout Sam68 mice. Fig. S3 shows a developmental analysis of testicular morphology in Sam68 wild-type and knockout mice. Fig. S4 shows phosphoH3 and Sam68 immunofluorescence analysis in control and OX-treated spermatocytes, and sucrose gradient fractionation of extracts from the same cells. Tables S1–S6 show the results of the microarray and IPA analyses of mRNAs from wild-type and knockout testes. Videos S1–S3 show the motility phenotype of wild-type and knockout spermatooza. Online supplemental material is available at http://www.jcb.org/cgi/content/full/jcb.200811138/DC1.

The authors wish to thank Dr. Jerome F. Strauss III for the generous gift of the anti-SpAg16 antibody, Dr. Harold Konig for the gift of the mycSam68L1 and RAS61Q plasmids, Dr. Maria Liaro for assistance with luciferase reporter assays, Dr. Flavia Botti for assistance with histochonmotheral analysis, Dr. Simona Pedotti for assistance with germ cell purification, and Amber Zabarasas for assistance with IPA analyses. We wish to thank Dr. Daniela Barilà and members of our laboratories for critical reading of the manuscript.

Figure S1. **Immunohistochemical analysis of Sam68 expression in adult mouse testis.** Testicular sections representing different stages of the cycle of mouse seminiferous tubules were stained with anti-Sam68 antibody and counterstained with hematoxylin to detect cell nuclei. Arrows indicate representative cells discussed in the text. The stage of the seminiferous tubule was assessed by staining an adjacent section with periodic acid-Schiff stain, and it is labeled on the top right of each panel. Sam68 protein accumulates from the mid-pachytene stage (Stage VI) to the stages approaching the meiotic divisions (stages X–XII). Stage XII tubules from Sam68 null testis were also stained to determine the specificity of the anti-Sam68 antibody in immunohistochemistry. Lp, leptotene; Pc, pachytene; Zg, zygotene. Bar, 100 µm.
Figure S2. **Analysis of the testicular phenotype and fertility of Sam68 knockout mice.** (A–C) Analysis of testis weight (A), whole body weight (B), and the ratio of testis/body weight (C) of Sam68+/+ (n = 14), Sam68+/− (n = 13), and Sam68−/− (n = 20) mice. *, P < 0.01 in t test and ANOVA test. (D) Testosterone levels in serum obtained from Sam68+/+ (n = 10), Sam68+/− (n = 8), and Sam68−/− (n = 15) mice. The bar represents the mean value; each symbol represents the actual concentration in each mouse analyzed. (E) Quantitative data of the percentage of each germ cell type as determined by propidium iodine staining in three independent experiments using adult mice (≥8 wk). *, P < 0.01 in t test. (F and G) Histological analysis on semithin sections of seminiferous tubules from wild-type (F) or knockout (G) testes. Arrows in G indicate the aberrant cells containing two or more nuclei in postmeiotic round spermatids. (H) Representative examples of in vitro fertilization experiments using wild-type oocytes and Sam68+/+ or Sam68−/− spermatozoa. 24 h after in vitro fertilization, 30–40% of eggs incubated with wild-type spermatozoa were fertilized and reached the two-cell stage of embryo development. By contrast, none of the eggs incubated with knockout spermatozoa were fertilized, and they all remained at the one-cell stage. Bars, 50 µm. (I) Diagram showing the results of three independent in vitro fertilization experiments using Sam68+/+, Sam68+/−, and Sam68−/− spermatozoa. Data are represented as the mean + SD.
Figure S3. **Histological analysis of testes from Sam68 knockout mice.** Histological analysis of testis from prepuberal mice (15 dpp), postpuberal mice (25 dpp), and mice that have completed the first wave of spermatogenesis (45 dpp). Arrows indicate round spermatids in the 25-dpp testes and elongated spermatids in the 45-dpp testes. Bar, 100 µm.
**Figure S4.** Effect of stimulation with okadaic acid of pachytene spermatocytes on the subcellular distribution of Sam68. Control (DMSO) or treated (OA) spermatocytes were analyzed by immunofluorescence with the anti-phosphoH3 (p-H3) antibody (A) or the anti-Sam68 antibody (B). Phosphorylated H3 staining indicates that spermatocytes have progressed to the M phase of the first meiotic division. Arrows in B indicate spermatocytes in which Sam68 is localized in the cytoplasm after OA treatment. Cells were also stained for DNA with Hoechst 33342. (A and B) Rightmost panels show the merged images of pH3 or Sam68 and DNA staining. (C) Absorbance profile (OD = 254 nm) of sucrose gradient sedimentation of cells extracts from control (DMSO) or treated (OA) mouse spermatocytes. The bottom panels show the Western blot analysis of Sam68 distribution in each fraction of the gradients.
Video 1. **Defects in spermiogenesis in Sam68 \(^{-/-}\) testis.** Motility is impaired in spermatozoa from Sam68 knockout mice (~50% of the animals tested). Most of the spermatozoa produced by Sam68 \(^{-/-}\) mice were abnormally shaped and immotile. Some spermatozoa displayed motility but the majority lost their flagellum shortly after their release in fertilization medium. Images were taken from an inverted microscope (DMI6000B; Leica) using a Pan-Neofluar 40×/0.75 objective lens. Images were acquired at room temperature using an RT-slider camera (Diagnostic Instruments, Inc.) and LIF software (Leica). The display rate is 5 frames per second.

Video 2. **Defects in spermiogenesis in Sam68 \(^{-/-}\) testis.** Motility is impaired in spermatozoa from Sam68 knockout mice (~50% of the animals tested). The few Sam68 \(^{-/-}\) spermatozoa that maintained reduced motility in culture were completely infertile even under in vitro fertilization conditions. Images were taken from an inverted microscope (DMI6000B; Leica) using a Pan-Neofluar 40×/0.75 objective lens. Images were acquired at room temperature using an RT-slider camera (Diagnostic Instruments, Inc.) and LIF software (Leica). The display rate is 5 frames per second.

Video 3. **Normal spermatozoa motility.** Movement of normal spermatozoa from a wild-type mouse contrasts with the impaired motility observed in spermatozoa from Sam68 knockout mice. Images were taken from an inverted microscope (DMI6000B; Leica) using a Pan-Neofluar 40×/0.75 objective lens. Images were acquired at room temperature using an RT-slider camera (Diagnostic Instruments, Inc.) and LIF software (Leica). The display rate is 5 frames per second.
