Primary microcephaly, Seckel syndrome, and microcephalic osteodysplastic primordial dwarfism type II (MOPD II) are disorders exhibiting marked microcephaly, with small brain sizes reflecting reduced neuron production during fetal life. Although primary microcephaly can be caused by mutations in microcephalin (MCPH1), cells from patients with Seckel syndrome and MOPD II harbor mutations in ataxia telangiectasia and Rad3 related (ATR) or pericentrin (PCNT), leading to disturbed ATR signaling. In this study, we show that a lack of MCPH1 or PCNT results in a loss of Chk1 from centrosomes with subsequently deregulated activation of centrosomal cyclin B–Cdk1.

Introduction

Primary microcephaly is a neurodevelopmental disorder characterized by reduced brain size. The first causative gene identified encodes microcephalin (MCPH1), a protein implicated in DNA damage signaling via ataxia telangiectasia and Rad3 related (ATR; Jackson et al., 2002; Alderton et al., 2006). Accordingly, the clinical features of MCPH1 syndrome patients resemble those of Seckel syndrome, another microcephalic disorder that can be caused by mutations in ATR or defective ATR signaling (O’Driscoll et al., 2003; Alderton et al., 2004). Recently, it has been reported that mutations in pericentrin (PCNT), resulting in the loss of PCNT from the centrosome, also cause Seckel syndrome (Griffith et al., 2008). PCNT-Seckel cells, like ATR-Seckel cells, show defects in ATR-dependent G2/M checkpoint control. This finding is further supported by the recent description of PCNT mutations in microcephalic osteodystrophic primordial dwarfism type II (MOPD II), a microcephalic disorder in which growth restriction is thought to be the consequence of mitotic failure (Rauch et al., 2008).

Mechanistically, it has been shown that MCPH1 prevents premature entry into mitosis and speculated that loss of PCNT might prevent centrosomal recruitment of the checkpoint kinase Chk1, an ATR target that controls initial activation of cyclin B–Cdk1 at the centrosome (Krämer et al., 2004; Alderton et al., 2006; Löffler et al., 2006a; Griffith et al., 2008). Activation of cyclin B–Cdk1 is the key event required for the initiation of mitosis (Nurse, 1990). Cdk1 and cyclin B accumulate at the centrosome during interphase (Bailly et al., 1989, 1992), where initial activation of the cyclin B–Cdk1 complex occurs in late prophase (Jackman et al., 2003). The accumulation of active cyclin B–Cdk1 within the nucleus shortly thereafter irreversibly commits the cell to mitosis. Therefore, regulation of cyclin B–Cdk1 activity at the centrosome is critical for controlling both cytoplasmic and nuclear mitotic events. During unperturbed cell cycles, activation of cyclin B–Cdk1 at the centrosome is mediated by Cdc25B (De Souza et al., 2000; Krämer et al., 2004), which itself is positively regulated by phosphorylation at S353 by aurora A and inhibited by Chk1-mediated S230 phosphorylation at centrosomes (Dutertre et al., 2004; Löffler et al., 2006b; Schmitt et al., 2006).

To directly address whether loss of Chk1 from centrosomes constitutes a mechanism for premature entry into mitosis in microcephaly syndromes, we examined both primary patient-derived...
cells from individuals with \textit{MCPH1}^{427insA} (MCPH1 syndrome) and \textit{PCNT}^{3109G>T} (MOPD II) mutations as well as cells treated with MCPH1- and PCNT-specific siRNAs, respectively.

Results and discussion

Chk1 is lost from centrosomes in both MCPH1- and PCNT-deficient cells

First, we analyzed whether deficiency of either MCPH1 or PCNT impacts on the abundance of Chk1 at centrosomes in human cells. Although immunofluorescence microscopy analysis with a monoclonal antibody against Chk1 revealed a pronounced centrosomal staining in both U2OS and control lymphoblastoid cells (LBCs), Chk1 levels were reduced at centrosomes in MCPH1 and PCNT siRNA–treated U2OS cells as well as in primary MCPH1\textsuperscript{427insA} and PCNT\textsuperscript{3109G>T} cells from patients with primary microcephaly or MOPD II, respectively (Fig. 1, A–C; and Fig. S1, A–C). This effect was independent from the cell cycle stage, as Chk1 levels were reduced to a similar extent in both cells containing a single centrosome, reflecting G\textsubscript{0}/G\textsubscript{1} phase, and two centrosomes, reflecting S/G\textsubscript{2} phase, respectively (Fig. S1 C). Virtually identical results were obtained when a rabbit polyclonal antibody against Chk1 was used (unpublished data).

Next, we examined the association of Chk1 with centrosomes using centrosome preparations from MCPH1\textsuperscript{427insA} as well as PCNT\textsuperscript{3109G>T} cells and normal LBCs. Although comparable protein amounts were loaded, the centrosome preparations from MCPH1\textsuperscript{427insA} and PCNT\textsuperscript{3109G>T} cells contained reduced levels of Chk1 as compared with centrosomes from control LBCs (Fig. 1 D). The loss of Chk1 from centrosomes in MCPH1- and PCNT-deficient cells was not attributable to a general shortage of cellular Chk1 in these cells, as whole cell lysates from control and MCPH1\textsuperscript{427insA} or PCNT\textsuperscript{3109G>T} LBCs contained almost identical Chk1 levels (Fig. 1 E). Likewise, we have described previously that Chk1 is lost from centrosomes during mitosis, although total cellular Chk1 levels are not reduced during this phase of the cell cycle (Krämer et al., 2004). On the basis of these combined in situ and biochemical analyses, we conclude that in MCPH1- and PCNT-deficient cells, Chk1 is lost from centrosomes.

MCPH1 targets Chk1 to the centrosome

How Chk1 is recruited to interphase centrosomes during unperturbed cell cycles remains unknown. MCPH1 has been reported to localize to centrosomes in chicken DT40 cells and to directly interact with Chk1 in vitro (Alderton et al., 2006; Jeffers et al., 2008), thereby possibly contributing to the localization of Chk1 to centrosomes. To test for this possibility, we first confirmed that endogenous human MCPH1 localizes to interphase centrosomes in control but not MCPH1\textsuperscript{427insA} LBCs or MCPH1 siRNA–treated U2OS cells by immunofluorescence microscopy using an antibody raised against an N-terminal fragment (1–267 aa) of MCPH1 (CCU.M1; see Materials and methods; Fig. 2 A and Fig. S1 D). Also, in contrast to MCPH1\textsuperscript{427insA} LBCs, MCPH1 was detectable in centrosome preparations from control LBCs (Fig. 2 B). Therefore, we conclude that MCPH1 indeed localizes to centrosomes.

To verify the interaction of MCPH1 with Chk1 in vivo, endogenous Chk1 was immunoprecipitated from U2OS cells transiently expressing MCPH1 fused to GFP (GFP-MCPH1), with GFP-MCPH1 being readily detectable in the immunoprecipitates (Fig. 2 C). Similarly, immunoprecipitation of GFP-MCPH1 using an anti-GFP antibody led to coimmunoprecipitation of endogenous Chk1. In contrast to the loss of centrosomal Chk1 in MCPH1-deficient cells, the centrosomal levels of MCPH1 remained virtually unchanged in U2OS cells transfected with Chk1 siRNA (Fig. 2 D), which is analogous to what has been reported for Chk1\textsuperscript{−/−} DT40 cells (Jeffers et al., 2008). Thus, we conclude that MCPH1 and Chk1 interact with each other and that MCPH1 targets Chk1 to the centrosome.

MCPH1-dependent recruitment of Chk1 to centrosomes is mediated by PCNT

As PCNT has an established role in targeting regulatory proteins to the centrosome (Diviani et al., 2000; Chen et al., 2004), direct or indirect binding of Chk1 by PCNT might mediate the centrosomal localization of Chk1 (Griffith et al., 2008). To determine whether the loss of Chk1 from centrosomes in MCPH1-deficient cells is a consequence of a shortage of centrosomal PCNT, control and MCPH1\textsuperscript{427insA} LBCs were immunostained for PCNT. In contrast to control LBCs, centrosomal PCNT signals were diminished in MCPH1\textsuperscript{427insA} cells (Fig. 3, A and B; and Fig. S2 A). Immunostaining of MCPH1 siRNA– and mock siRNA–treated U2OS cells with antibodies to PCNT led to similar results. Consistently, centrosome preparations from MCPH1\textsuperscript{427insA} cells contained less PCNT as compared with control LBCs (Fig. 2 B). Also, GFP-MCPH1 coimmunoprecipitated with endogenous PCNT when transiently expressed in U2OS cells (Fig. S2 B). Similarly, immunoprecipitation of GFP-MCPH1 led to coimmunoprecipitation of endogenous PCNT. Thus, MCPH1 and PCNT interact with each other, and in addition to a loss of centrosomal Chk1, PCNT is depleted from centrosomes in MCPH1-deficient cells. To the contrary, PCNT deficiency did not impact on the abundance of MCPH1 at centrosomes in PCNT\textsuperscript{3109G>T} or PCNT siRNA–treated U2OS cells (Fig. 2 A). Also, the centrosomal levels of PCNT remained unchanged in both U2OS cells transfected with Chk1 siRNA and Chk1\textsuperscript{−/−} DT40 cells (Fig. 3 C; Zachos et al., 2003).

To examine the relationship between PCNT and Chk1 in more detail, endogenous PCNT was immunoprecipitated from control and MCPH1\textsuperscript{427insA} LBCs, respectively. Endogenous Chk1 was detectable in immunoprecipitates from both cell types (Fig. 3 D). Similarly, immunoprecipitation of endogenous Chk1 led to coimmunoprecipitation of endogenous PCNT. Thus, PCNT and Chk1 interact with each other independent from the presence of MCPH1. Collectively, we conclude that MCPH1 contributes to the centrosomal localization of PCNT and that both MCPH1 and PCNT are required to recruit Chk1 to the centrosome.

To further confirm an interaction between Chk1, MCPH1, and PCNT, we size fractionated whole cell lysates from U2OS cells transiently transfected with GFP-MCPH1 by Superose 6 gel filtration chromatography (Fig. 3 E). As additional evidence for complex formation, all three proteins comigrated.
MCPH1 or PCNT depletion-induced loss of Chk1 protein in isolated centrosome preparations. Immunoblots were performed on three sucrose gradient fractions of centrosome preparations (left) and whole cell lysates (right) as an input control from normal, MCPH1427insA, and PCNT3109G>T LBCs using antibodies against Chk1 and, for comparison, Nek2 (a centrosomal protein) and Mcm7 (a nuclear protein). For whole cell lysates, actin was included as a loading control. (E) Western blot analysis of PCNT, MCPH1, and Chk1 in whole cell lysates from control, MCPH1427insA, and PCNT3109G>T LBCs. Actin was included as a loading control. Arrowheads point to centrosomes, which are shown enlarged in insets.

LOST OF CENTROSOMAL CHK1 IN MICROCEPHALY SYNDROMES • Tibelius et al. 1151

We next examined other components of the centrosome to establish whether they were affected by the absence of MCPH1 or PCNT (Fig. S2, C and D). Centrin, Nek2, and Cep170 were all localized normally. However, γ-tubulin was significantly reduced at interphase centrosomes in MCPH1427insA and PCNT3109G>T LBCs as compared with control LBCs, which is consistent with what has been described for mitotic PCNT-Seckel cells (Griffith et al., 2008).

Figure 1. Chk1 levels are reduced at centrosomes in both MCPH1- and PCNT-deficient cells. (A) Normal, MCPH1427insA, and PCNT3109G>T LBCs as well as U2OS cells transfected with luciferase (as control [siLUC]), MCPH1-, or PCNT-specific siRNA were costained with mouse anti-Chk1 (red) and rabbit anti-γ-tubulin (green) antibodies and analyzed by confocal microscopy. Bar, 10 µm. (B) The mean percentages of cells with centrosomal colocalization of γ-tubulin and Chk1 are indicated. Error bars represent the standard deviation after combining the results of three different experiments. Statistical significance versus control (LBC) by two-tailed Student's t test is as follows: ***, P = 9 × 10⁻⁶ (MCPH1427insA); P = 0.00003 (PCNT3109G>T). (C) Quantification of pixel intensity profiles constructed from optically sectioned (z axis) fluorescence images of control, MCPH1427insA, and PCNT3109G>T LBCs. Error bars represent standard deviations from the analysis of 100 cells. Statistical significance versus control (LBC) by two-tailed Student's t test is as follows: ***, P = 1.4 × 10⁻⁷ (MCPH1427insA); P = 9.8 × 10⁻¹² (PCNT3109G>T). (D) Loss of Chk1 protein in isolated centrosome preparations. Immunoblots were performed on three sucrose gradient fractions of centrosome preparations (left) and whole cell lysates (right) as an input control from normal, MCPH1427insA, and PCNT3109G>T LBCs using antibodies against Chk1 and, for comparison, Nek2 (a centrosomal protein) and Mcm7 (a nuclear protein). For whole cell lysates, actin was included as a loading control. (E) Western blot analysis of PCNT, MCPH1, and Chk1 in whole cell lysates from control, MCPH1427insA, and PCNT3109G>T LBCs. Actin was included as a loading control. Arrowheads point to centrosomes, which are shown enlarged in insets.

together in two fractions, which correspond to a molecular mass of >2 MD.

MCPH1 or PCNT depletion-induced loss of Chk1 from centrosomes leads to premature activation of cyclin B-Cdk1

Centrosome-associated Chk1 prevents premature activation of cyclin B–Cdk1 and thereby mitotic entry by inhibitory phosphorylation of centrosomal Cdc25B at S230 with consecutive inhibition of P-Y15-Cdk1 dephosphorylation (Krämer et al., 2004; Schmitt et al., 2006). To determine whether down-regulation of MCPH1 or PCNT has an impact on the phosphorylation status of the centrosomal fractions of Cdc25B and Cdk1, primary
MCPIH<sup>427insA</sup> and PCNT<sup>3109G>T</sup> LBCs as well as control LBCs were synchronized in G1/early S phase by a mimosine block and released for 8 h to reach G2 phase. Subsequently, cells were co-immunostained with antibodies to P-S230-Cdc25B or P-Y15-Cdk1 and γ-tubulin. Although centrosomes were decorated with anti–P-S230-Cdc25B in 65.7 ± 5.1% in control LBCs, only 14.0 ± 2.6% and 36.7 ± 1.5% of MCPIH<sup>427insA</sup> and PCNT<sup>3109G>T</sup> LBCs harbored centrosomes that stained positive for P-S230-Cdc25B (Fig. 4, A and B). Similarly, in contrast to control LBCs (27.3 ± 5.1%), only 5.7 ± 1.5% and 10.0 ± 1.7% of MCPIH<sup>427insA</sup> and PCNT<sup>3109G>T</sup> LBCs, respectively, harbored centrosomes with discernible P-Y15-Cdk1 decoration, despite almost all centrosomes stained positive for total Cdk1 (Fig. 4, C–E).

Next, we examined the phosphorylation status of Cdc25B and Cdk1 using centrosome preparations from MCPIH<sup>427insA</sup> as well as PCNT<sup>3109G>T</sup> cells and normal LBCs. Although comparable protein amounts were loaded, the centrosome preparations from MCPIH<sup>427insA</sup> and PCNT<sup>3109G>T</sup> cells contained reduced levels of P-S230-Cdc25B or P-Y15-Cdk1 as compared with control LBCs (Fig. 4 F). Similar to immunofluorescence stainings, reduced levels of P-Y15-Cdk1 at centrosomes in MCPIH- and PCNT-deficient cells were not attributable to a general shortage of centrosomal Cdk1 in these cells, as centrosome preparations from control and MCPIH<sup>427insA</sup> or PCNT<sup>3109G>T</sup> LBCs contained almost identical Cdk1 levels (Fig. 4 F).

Figure 2. MCPIH1 interacts with and targets Chk1 to the centrosome. (A) Control, MCPIH<sup>427insA</sup>, and PCNT<sup>3109G>T</sup> LBCs as well as U2OS cells transfected with luciferase- or MCPH1-specific siRNA were costained with mouse anti-MCPH1 (red) and rabbit anti-γ-tubulin (green) antibodies and analyzed by confocal microscopy. (B) Reduced levels of PCNT in isolated centrosome preparations from MCPIH<sup>427insA</sup> LBCs. Immunoblots were performed on three sucrose gradient fractions of centrosome preparations (left) and whole cell lysates (right) as an input control from normal, MCPIH<sup>427insA</sup>, and PCNT<sup>3109G>T</sup> LBCs using antibodies against PCNT, MCPH1, and, for comparison, Nek2 as a loading control and Mcm7 to exclude nuclear contamination. For whole cell lysates, actin was included as a loading control. (C) Transiently expressed GFP-MCPH1 and Chk1 interact with each other in vivo. Chk1 was immunoprecipitated from U2OS cells 2 h after transient transfection with GFP-MCPH1. Reciprocally, GFP-MCPH1 was immunoprecipitated using an anti-GFP antibody. Immunoprecipitation with an anti-HA antibody served as a negative control. Input represents 10% of the amount used for immunoprecipitation. White lines indicate that intervening lanes have been spliced out. (D) Depletion of Chk1 does not impact on centrosomal MCPIH1 levels. U2OS cells transfected with either luciferase- or Chk1-specific siRNA were costained with mouse anti-MCPH1 (red) and rabbit anti-γ-tubulin (green) antibodies (top) or mouse anti-Chk1 (red) and rabbit anti-γ-tubulin (green) antibodies (bottom) and analyzed by confocal microscopy. Arrowheads point to centrosomes, which are shown enlarged in insets. Bars, 10 µm.
human and *Drosophila melanogaster* MCPH1-deficient cells have low levels of total P-Y15-Cdk1 in S and G2 phases, resulting in accelerated mitotic entry in MCPH1427insA LBCs and premature centrosome separation in *MCPH1* mutant *Drosophila* embryos (Alderton et al., 2006; Brunk et al., 2007). To assay for the rates of cells in late G2 or mitosis, U2OS cells treated with mock-, MCPH1-, or PCNT-specific siRNAs were examined by flow cytometry measurement using P-S10-histone H3 as a mitotic marker. 72 h after MCPH1 or PCNT siRNA transfection, significantly more cells were in late G2 or mitosis (Fig. 5 A). Similar results were obtained when the cell cycle distribution of exponentially growing control, MCPH1427insA, and PCNT3109G>T LBCs was examined (Fig. 5 B and Fig. S3 A). In addition, transient transfection of MCPH1427insA LBCs with wild-type MCPH1-Flag

**Figure 3.** *MCPH1 recruits Chk1 to the centrosome via PCNT.* (A) Centrosomal PCNT levels are reduced in MCPH1427insA and PCNT3109G>T LBCs relative to control lymphoblasts. Normal, MCPH1427insA, and PCNT3109G>T LBCs as well as U2OS cells transfected with luciferase- as control (siLUC), MCPH1-, or PCNT-specific siRNA were costained with rabbit anti-PCNT (green) and mouse anti-γ-tubulin (red) antibodies and analyzed by confocal microscopy. (B) Quantification of pixel intensity profiles constructed from optically sectioned (z axis) fluorescence images of normal cells. Error bars represent standard deviations from the analysis of 100 cells. Statistical significance versus control (LBC) by two-tailed Student’s t test is as follows: ***, P = 7.2 × 10^-6* (MCPH1427insA). (C) Control and Chk1^-/-^ chicken DT40 cells as well as U2OS cells transfected with luciferase- or Chk1-specific siRNA were costained with rabbit anti-PCNT (green) and mouse anti-γ-tubulin (red) and analyzed by confocal microscopy. (D) Endogenous PCNT and Chk1 interact with each other in vivo. Endogenous Chk1 was detected in immunoprecipitates using an anti-PCNT antibody in both control and MCPH1427insA LBCs. Reciprocally, endogenous PCNT was detectable after immunoprecipitation of Chk1 in both cell lines as well. Immunoprecipitation with an anti-HA antibody served as a negative control. Input represents 10% of the amount used for immunoprecipitation. White lines indicate that intervening lanes have been spliced out. (E) Co-fractionation of PCNT, MCPH1, and Chk1 in U2OS whole cell lysates. Lysates were prepared from U2OS cells transiently transfected with GFP-MCPH1 24 h before lysis and size fractionated by fast protein liquid chromatography using a Superose 6 column. Proteins from consecutive fractions were analyzed by Western blotting using antibodies to PCNT, GFP, and Chk1. The size of marker proteins is shown on top. Numbers in red indicate the fractions that contain all three proteins (GFP-MCPH1, PCNT, and Chk1). Arrowheads point to centrosomes, which are shown enlarged in insets. Bars, 10 µm.
Figure 4. Loss of Chk1 from centrosomes induces activation of centrosome-associated Cdc25B and Cdk1. (A, C, and D) Normal, MCPH1427insA, and PCNT3109G>T LBCs were synchronized in G1/early S phase by a mimosine block, released for 8 h to reach G2 phase, and subsequently costained with rabbit anti–P-S230-Cdc25B (green) and mouse anti–γ-tubulin (red) antibodies (A), rabbit anti–P-Y15-Cdk1 (green) and mouse anti–γ-tubulin (red) antibodies (C), or mouse anti-Cdk1 (red) and rabbit anti–γ-tubulin (green) antibodies (D) and analyzed by confocal microscopy. (B) Loss of Chk1 from centrosomes induces activation of centrosome-associated Cdc25B. The mean percentages of cells with centrosomal colocalization of γ-tubulin and P-S230-Cdc25B are indicated. Statistical significance versus control (LBC) by two-tailed Student’s t test is as follows: ***, P = 0.0006 (MCPH1427insA); **, P = 0.006 (PCNT3109G>T). (E) Loss of Chk1 from centrosomes induces activation of centrosome-associated Cdk1. The mean percentages of cells with centrosomal colocalization of γ-tubulin and total Cdk1 (light gray bars) or P-Y15-Cdk1 (dark gray bars) are indicated. Statistical significance versus control (LBC) by two-tailed Student’s t test is as follows: *, P = 0.013 (MCPH1427insA); P = 0.019 (PCNT3109G>T). (F) Reduced levels of P-S230-Cdc25B and P-Y15-Cdk1 in isolated centrosome preparations from MCPH1427insA and PCNT3109G>T LBCs. Immunoblots were performed on three sucrose centrifugation fractions of centrosome preparations (left) and whole cell lysates (right) as an input control from control (LBC), MCPH1427insA, and PCNT3109G>T LBCs using antibodies against P-S230-Cdc25B, P-Y15-Cdk1, Cdk1, and, for comparison, Nek2 as a loading control and Mcm7 to exclude nuclear contamination. For whole cell lysates, antibodies to Cdc25B, Cdk1, and actin were included. Arrowheads point to centrosomes, which are shown enlarged in insets. Error bars represent the standard deviation after combining the results of three different experiments. Bars, 10 µm.
led to a significant reduction of G2/mitotic cells from 1.28 ± 0.2% after mock transfection to 0.75 ± 0.1% 12 h after transfection with MCPH1-Flag (Fig. S3 B).

Time-lapse video microscopy of MCPH1 and PCNT siRNA–treated U2OS cells revealed that mitosis in these cells was prolonged as compared with U2OS cells treated with luciferase siRNA (Fig. S3, C–E). After PCNT siRNA treatment, the frequency of cells dying out of mitosis was increased as well.

**Forced immobilization of Chk1 at centrosomes leads to accumulation of MCPH1-deficient cells with premature chromosome condensation (PCC) in G2 phase**

MCPH1 deficiency leads to a striking elevation in G2 phase–like cells with PCC mediated by deregulated activity of nuclear condensin II (Trimborn et al., 2004, 2006; Alderton et al., 2006). If MCPH1 indeed functions to locally regulate activation of Cdk1 via centrosomal targeting of Chk1, then specific interference with centrosome-associated Chk1 should alter the impact of MCPH1 depletion on the G2/M transition. To address this issue, we took advantage of a U2OS clone conditionally expressing GFP-Chk1 fused to the PCNT-AKAP450 centrosomal-targeting (PACT) domain of AKAP450, an immobile protein of the pericentriolar matrix (Gillingham and Munro, 2000; Krämer et al., 2004). In these cells, forced immobilization of wild-type Chk1 to centrosomes impairs activation of centrosome-associated Cdk1 and thereby entry into mitosis (Krämer et al., 2004). In these cells, forced immobilization of wild-type Chk1 to centrosomes impairs activation of centrosome-associated Cdk1 and thereby entry into mitosis (Krämer et al., 2004). When parental U2OS cells as well as wild-type and kinase-dead versions of GFP-Chk1-PACT–expressing cells were transfected with MCPH1-specific siRNA, 34.0 ± 5.5% of wild-type but only 14.2 ± 3.9% of kinase-dead GFP-Chk1-PACT–expressing cells and 16.2 ± 2.3% of parental U2OS cells showed a PCC phenotype 72 h after transfection (Fig. 5, C and D). These findings suggest that down-regulation of MCPH1 induces premature entry into mitosis via depletion of the centrosomal pool of Chk1. Forced immobilization of Chk1 at the centrosome prevents cell cycle progression into mitosis, leading to accumulation of cells with PCC in G2 phase.
In addition to MCPH1, three other primary microcephaly genes have been identified, ASPM, CENPJ, and CDK5RAP2 (Bond et al., 2002, 2005; Bond and Woods, 2006). Their protein products have a centrosomal localization in common and are required for centrosomal function. Therefore, a unifying theme for primary microcephaly of genes functioning in the process of cell division has been proposed. However, in contrast to mutations in TIP, MCPH1, and PCNT, which can reduce both body and brain size, effects of ASPM, CENPJ, and CDK5RAP2 mutations are restricted to the brain, presumably by acting specifically on neurogenic mitosis (Bond et al., 2005). Our data provide evidence that the recruitment of Chk1 to centrosomes depends on both MCPH1 and PCNT during unperturbed cell cycle progression. In MCPH1 syndrome and MOPD II, which result from mutations in MCPH1 and PCNT, respectively, loss of Chk1 from centrosomes leads to unscheduled entry into mitosis. Consequently, loss of regulatory restraints on the initial activation of cyclin B–Cdk1 at the centrosome might be a common final path in microcephalic disorders with reduced body size, thereby explaining for the first time why seemingly unrelated genetic defects result in a common human disease phenotype.

Materials and methods

Cell culture

U2OS cells were maintained in DME with 10% FCS. Control, MCPH1, and PCNT LBCs (Alderton et al., 2006; Rauch et al., 2008) were cultured in RPMI 1640 supplemented with 15% FCS. Derivatives of U2OS cells conditionally expressing wild-type or kinase-dead alleles of Gsk3p, Chk1-APC1 were generated as reported previously (Krämer et al., 2004). DT40 cells were maintained in RPMI 1640 with 10% chicken serum (Sigma-Aldrich).

Mimosine release

Cells were incubated overnight in 0.2 mM mimosine for synchronization at Chk1–PACT were generated as reported previously (Krämer et al., 2004). MCPH1 cDNA (GenBank/EMBL/DDBJ accession no. NM_024596) was cloned into pEGFP-C1 (Clontech Laboratories, Inc.) containing an N-terminal GFP tag as well as into pCMVTag4A (Agilent Technologies) containing a C-terminal Flag tag.

Antibodies

A phospho-specific rabbit antisera to S230-Cdc25B (SE4394) was raised and characterized as described previously (Schmitt et al., 2006). Mouse monoclonal antibodies to Cdk1 and GFP (B-2), rabbit antisera to actin (I-19), Chk1 (FL-476), and HA (Y11) as well as goat and donkey antisera to HRP were obtained from Santa Cruz Biotechnology, Inc.; a mouse monoclonal antibody to y-tubulin (TU-30) was obtained from Exbio; a mouse monoclonal antibody to Nek2 was obtained from BD; a goat antisera to MCPH1 was obtained from R&D Systems; rabbit antisera to PCNT, P-Y15-Cdk1, and P-S10–histone H3 were obtained from Abcam, EMD, and Millipore, respectively. Mouse monoclonal antibodies to centrin, Cep170, and lamin A were provided by J.L. Salisbury (Mayo Clinic, Rochester, MN), E.A. Nigg (University of Basel, Basel, Switzerland), and H. Herrmann-Lorden (German Cancer Research Center, Heidelberg, Germany), respectively. Highly cross-absorbed secondary reagents Alexa Fluor 488 and 568 were obtained from Invitrogen.

RNA interference

For siRNA-mediated ablation of Chk1, MCPH1, and PCNT, U2OS cells were transfected twice (at 0 and 24 h) with the following oligonucleotide sequences: Chk1 siRNA, 5′-GGAGGUUGAAGAGAAGATCt3′; MCPH1 siRNA, 5′-AAgAGGUGAAAGAGAAGATCt3′; PCNT siRNA, 5′-GCA-GCGUGGCAAGAGGADt3′; and luciferase siRNA, 5′-UAAACGCU-AUGAAGGAGAUACd3′ by Oligofectamine reagent (Invitrogen). Cells were harvested 72 h after the first transfection.

Isolation and analysis of human centrosomes

Centrosomes were isolated from control, MCPH1427tna and PCNT109G-T LBCs as described previously (Moudjou and Bornens, 1994).

Gel filtration

Whole cell lysates were cleared by centrifugation and passaged through a 0.2-µm filter. 200 µl cleared lysate was applied to a Superose 6 gel filtration column (HR 10/30; GE Healthcare) and resolved on a fast protein liquid chromatography system (GE Healthcare) according to the manufacturer’s instructions.

Immunoprecipitation

For immunoprecipitation, cells were lysed with RIPA buffer (50 mM Tris, pH 8.0, 500 mM NaCl, 1% NP-40, 0.2 mM EDTA, 5 mM NaF, and 1 mM Na3VO4) containing a protease inhibitor cocktail (Roche). Supernatants of the cell lysates were centrifuged at 14,000 g for 20 min. Precipitating antibodies were preincubated with protein G/A agarose beads (50% slurry; Roche) for 1 h at room temperature followed by three washes for 5 min each in RIPA buffer and overnight incubation at 4°C after adding aliquots of the cell lysate supernatant. Negative controls were generated by immunoprecipitation with an antibody to HA (Clontech Laboratories, Inc.). After three washes for 5 min each in RIPA buffer, the proteins were analyzed by immunoblotting.

Transfection

U2OS cells were transiently transfected with 2 µg pEGFP-C1-MCPH1 using Fugene 6 (Roche) and MCPH1427tna LBCs with 1.5 µg pCMVTag4A-MCPH1 by electroporation using a MicroPorator (MP-100; Peqlab) according to the manufacturer’s instructions.

Generation of an MCPH1-specific monoclonal antibody

A bacterially expressed and affinity-purified His-tagged MCPH1 fragment (MCPH1-1, 267aa-His) was used to immunize mice following a modified standard immunization protocol (Köhler and Milstein, 1975). Fusions resulted in the generation of six specific monoclonal antibodies that were subsequently cloned. Specificity of the antibody that was eventually used for further experiments [CCU.M1], which was typed as mouse IgM, was verified by using bacterially expressed recombinant proteins as well as control and MCPH1427tna LBCs for Western blotting and U2OS cells for immunofluorescence staining.

Live cell imaging

Live cell imaging of cells growing in CO2-independent Leibovitz medium (Invitrogen) on microdishes (Ibidi) was performed at 37°C in a humidified atmosphere containing 5% CO2 using the BioStation IM system (Nikon) equipped with a 63× 0.8 NA Plan Fluor objective (Nikon).
Flow cytometry

Cell cycle analysis by flow cytometry including the quantification of cells in mitosis by P-S10–histone H3 staining was performed as previously described [Rebacz et al., 2007].

Online supplemental material

Fig. S1 presents a time course of siRNA-mediated depletion of PCNT and MCPH1 as well as a characterization of a novel anti-MCPH1 antibody and illustrates that Chk1 levels are reduced at centrosomes in both MCPH1- and PCNT-deficient cells. Fig. S2 illustrates that centrosomal PCNT levels are reduced in MCPH1 [27%] and PCNT [10%] BLCs irrespective of their cell cycle status, that transiently expressed GFP-MCPH1 and endogenous PCNT interact with each other in vivo, and that centrosomal levels of centrin, Nek2, and Cep170, but not tubulin, are unchanged in MCPH1- and PCNT-deficient cells. Fig. S3 depicts the cell cycle distribution of MCPH1 [27%] and PCNT [10%] BLCs, demonstrates that rescue of MCPH1 [27%] BLCs via transfection with wild-type MCPH1-Flag leads to a restored mitotic index, and outlines the mitotic fate of MCPH1- and PCNT-depleted U2OS cells. Online supplemental material is available at http://www.jcb.org/cgi/content/full/jcb.200810159/DC1.

We thank D.A. Gillespie for providing Chk1[1-104] DT40 cells, J.L. Salisbury, E.A. Nigg, and H. Hermannsdorfer for providing antibodies to centrin, Cep170, and lamin A, respectively, S. Pappelpleuer [Carl Zeiss, Inc., Heidelberg, Germany] for technical support, and B. Schreiter and S. Franz for excellent technical assistance.

We are grateful to the Deutsche Forschungsgemeinschaft and the European Commission [project Genome Instability in Cancer and Precancer] for financial support.

Figure S1. **Chk1 levels are reduced at centrosomes in both MCPH1- and PCNT-deficient cells.** (A) Time course of siRNA-mediated depletion of PCNT and MCPH1. U2OS cells transfected with the indicated siRNAs were analyzed by Western blotting 24, 48, and 72 h after transfection with PCNT and MCPH1 (R&D Systems) antibodies. Actin is included as a loading control. (bottom) The arrow marks MCPH1. The faster migrating band is caused by unspecific staining of the anti-MCPH1 antibody used for the experiment. (B and C) Chk1 levels are reduced at centrosomes in both MCPH1- and PCNT-deficient cells. (B) Semiquantitative pixel intensity profiles of centrosomes produced from optically sectioned (z axis) fluorescence images show depletion of centrosomal Chk1 in both MCPH1427insA and PCNT3109G>T LBCs as compared with control LBCs. Color indicates staining intensity. (bottom) 2D projections of the respective 3D z-stack reconstructions are shown. (C) Quantification of pixel intensity profiles constructed from optically sectioned (z axis) fluorescence images of normal (LBC), MCPH1427insA, and PCNT3109G>T LBCs with either a single centrosome, reflecting G0/G1 phase, or two centrosomes, reflecting S/G2 phase, respectively. Bars and error bars represent means and SD from the analysis of 100 cells. Statistical significance versus control (LBC) by two-tailed Student’s t test is as follows: **, P = 0.007 (MCPH1427insA [G0/G1]); ***, P = 3.10^{-6} (MCPH1427insA [S/G2]); P = 6.5 \times 10^{-4} (PCNT3109G>T [G0/G1]); P = 2.3 \times 10^{-11} (PCNT3109G>T [S/G2]). (D) Characterization of anti-MCPH1 antibody. Antibody clone CCU.M1 directed against MCPH1 was tested by Western blotting against whole cell lysates of control (LBC), MCPH1427insA, and PCNT3109G>T LBCs.
Figure S2.  **PCNT interacts with MCPH1 and is reduced at centrosomes in MCPH1-deficient cells irrespective of their cell cycle status.** (A) Centrosomal PCNT levels are reduced in MCPH1^{427insA} and PCNT^{3109G>T} LBCs irrespective of their cell cycle status. Quantification of pixel intensity profiles constructed from optically sectioned (z axis) fluorescence images of normal (LBC), MCPH1^{427insA}, and PCNT^{3109G>T} LBCs with either a single centrosome, reflecting G0/G1 phase, or two centrosomes, reflecting S/G2 phase, respectively. Statistical significance versus control (LBC) by two-tailed Student’s *t* test is as follows: ***P = 2.8 \times 10^{-2} (MCPH1^{427insA} [S/G2]);*** **P = 7.7 \times 10^{-3} (MCPH1^{427insA} [G0/G1]);** P = 5.10^{-12} (MCPH1^{427insA} [S/G2]); P = 4.6 \times 10^{-8} (PCNT^{3109G>T} [G0/G1]); P = 8.3 \times 10^{-17} (PCNT^{3109G>T} [S/G2]). (B, top) Transiently expressed GFP-MCPH1 and endogenous PCNT interact with each other in vivo. PCNT was immunoprecipitated from U2OS cells 24 h after transient transfection with GFP-MCPH1. (bottom) Reciprocally, GFP-MCPH1 was immunoprecipitated using an anti-GFP antibody. Both endogenous PCNT and GFP-MCPH1 were detectable as coimmunoprecipitates. For comparison, GFP-MCPH1 and PCNT were not detectable after immunoprecipitation with an anti-HA antibody. Input represents 10% of the amount used for immunoprecipitation. (C and D) Centrosomal levels of centrin, Nek2, Cep170, and γ-tubulin in both MCPH1- and PCNT-deficient cells. (C) Control (LBC), MCPH1^{427insA}, and PCNT^{3109G>T} LBCs were immunostained with antibodies as indicated in the figures and analyzed by confocal microscopy. Arrowheads indicate centrosomes. Bars, 10 µm. (D) Quantification of pixel intensity profiles constructed from optically sectioned (z axis) fluorescence images of normal (LBC), MCPH1^{427insA}, and PCNT^{3109G>T} LBCs with either a single centrosome, reflecting G0/G1 phase, or two centrosomes, reflecting S/G2 phase, respectively, demonstrating that centrosomal γ-tubulin levels are reduced in both MCPH1^{427insA} and PCNT^{3109G>T} LBCs in a cell cycle-independent manner. Statistical significance versus control (LBC) by two-tailed Student’s *t* test is as follows: ***P = 7.7 \times 10^{-3} (MCPH1^{427insA} [G0/G1]);** P = 5.10^{-12} (MCPH1^{427insA} [S/G2]); P = 4.6 \times 10^{-8} (PCNT^{3109G>T} [G0/G1]); P = 8.3 \times 10^{-17} (PCNT^{3109G>T} [S/G2]). Bars and error bars represent means and SD from the analysis of 100 cells.
Figure S3. **Cell cycle distribution and mitotic fate of MCPH1- and PCNT-deficient cells.** (A) Cell cycle distribution of control, MCPH1^{427insA}, and PCNT^{3109G>T} LBCs. Normal, MCPH1^{427insA}, and PCNT^{3109G>T} LBCs were stained with propidium iodide and anti–P-S10–histone H3 and analyzed by fluorescence-activated cell sorting. Cell cycle histogram plots (top) and 2D dot plots showing propidium iodide against anti–P-S10–histone H3 staining (bottom) of a representative experiment are depicted. Percentages of cells in G0/G1, S, and G2/M phase (top) and mitotic cells (bottom) are given as mean ± SD from three independent experiments. (B) Rescue of MCPH1^{427insA} LBCs via transfection with wild-type MCPH1-Flag leads to a restored mitotic index. MCPH1^{427insA} LBCs were transfected with Flag or MCPH1-Flag by electroporation (MicroPorator MP-100, Peqlab), costained with propidium iodide and anti–P-S10–histone H3, and analyzed by fluorescence-activated cell sorting to quantify cells in mitosis 12 h after transfection. DNA histograms (top) and histone H3 phosphorylation versus DNA content (bottom) in Flag- (left) and MCPH1-Flag–transfected (right) MCPH1^{427insA} LBCs. The results of a representative experiment are shown. Percentages of cells in G0/G1, S, and G2/M phase (top) and mitotic cells (bottom) are given as mean ± SD from three independent experiments. Statistical significance versus control by two-tailed Student’s t-test is P = 0.019. (C-D) Mitotic fate of MCPH1- and PCNT-depleted U2OS cells. U2OS cells were transfected with luciferase- (as control [siLUC]) or MCPH1- and PCNT-specific siRNA and subjected to time-lapse video microscopy starting 72 h after the first transfection. Representative examples for luciferase-, MCPH1-, or PCNT-specific siRNA-transfected cells displaying a normal, prolonged, and failing mitosis are shown in C. Bars, 20 µm. Results revealed that mitosis was prolonged (D and E) or completely failed (E) in increased proportions in U2OS cells transfected with MCPH1- and PCNT-specific siRNA as compared with control cells. Bars and error bars represent means and SD from the analysis of 100 mitotic cells (D) or from three independent experiments (E). Statistical significance versus control (LBC) by two-tailed Student’s t-test as follows: *, P = 0.01 (MCPH1^{427insA} [normal mitosis]); P = 0.03 (MCPH1^{427insA} [delayed mitosis]); P = 0.01 (PCNT^{3109G>T} [mitotic death]); P = 0.025 (PCNT^{3109G>T} [delayed mitosis]); **, P = 0.001 (PCNT^{3109G>T} [normal mitosis]).
